MINNESOTA MEDICINE

Journal of the Minnesota State Medical Association, Southern Minnesota Medical Association, Northern Minnesota Medical Association, Minnesota Academy of Medicine, and Minneapolis Surgical Society

Owned and Published by
THE MINNESOTA STATE MEDICAL ASSOCIATION

Under the Direction of Its

EDITING AND PUBLISHING COMMITTEE

E. M. Hammes, M.D., Chairman, St. Paul
T. A. Peppard, M.D., Secretary, Minneapolis
A. H. Wells, M.D., Duluth
H. A. Roust, M.D., Montevideo
C. L. Oppegaard, M.D., Crookston
Philip F. Donohue, M.D., St. Paul
Henry L. Ulrich, M.D., Minneapolis
O. W. Rowe, M.D., Duluth
H. W. Meyerding, M.D., Rochester
B. O. Mork, Jr., M.D., Worthington

EDITOR
Carl B. Drake, M.D., Saint Paul

ASSOCIATE EDITORS
George Earl, M.D., Saint Paul
Henry L. Ulrich, M.D., Minneapolis

VOLUME 29

JANUARY — DECEMBER, 1946

EDITORIAL AND BUSINESS OFFICES
2642 University Avenue - - - - - - - - - - - Saint Paul 4, Minn.

BUSINESS MANAGER

J. R. Bruce

Index to Volume 29

A

Abdomen, Acute lesions of the, 317
Acceleration of bone production by use of ground bone, The, 328
Acromio-clavicular joint dislocation, Acute, 357
Acute acromio-clavicular joint dislocation, 357
Acute hemorrhagic pancreatitis, 1047
Acute lesions of the abdomen, 317
Acute non-malignant perforations of the colon, 935
Air embolism, 1238
Aita, John A.: The evaluation and management of recurrent headaches, 568
Alden, John, Burt, Georgie M., Spink, Wesley W., and Hall, Wendell H.: The treatment of pneumococcic and staphylococcic meningitis with penicillin and sulfonamides, 553
Alexander, H. A., and McPheeters, H. O.: Lumbar sympathetic block and that postphlebitic leg, 43
Allergy, Ethylene disulphonate in, 690
Anderson, Gaylord W.: Military diseases in civilian life, 1105
Anderson, James K.: The significance of bleeding from the rectum, 274
Anemia, pernicious, The cytology of the erythrogenic reticulum of the bone marrow in, before and after administering folic acid, 1212
Anesthesia, ether, The centenary of the demonstration of, 993
Anticoagulant therapy in postoperative thrombophlebitis and pulmonary embolism, 778
Antiluetic therapy, Effect of, on bundle branch block (case report), 582
Appendicitis—personal experiences, 1038
Arestad, F. H.: Medical service in the community hospital, 1117
Arterial occlusion, acute, of the extremities, The treatment of, with special reference to anticoagulant therapy, 250
Artery, iliac, Ureteral obstruction caused by aneurysm of the, 143
Artery, right femoral, Embolism of the, 66
Athens, A. G.: Vertigo in hypothyroidism, 562
Atypical chronic glomerulonephritis, 1218
"Atypical lichen planus," Blood dyscrasia with and without associated, 575
Appendices, Normal, in 1,000 appendectomies, 1019
Artificial sphincter—a new operation and device for control of urinary incontinence and nocturnal enuresis, 1041

B

Bacillary dysentery, 1108
Backus, R. W.: Tropical disease hazards in the Northwest, 227
Baggenstoss, Archie H., Keith, Norman M., and Daugherty, Guy W.: Atypical chronic glomerulonephritis, 1218
Bagley, C. M., and Bagley, W. R.: Ruptured diverticulum of the jejunum, 691
Bagley, W. R., and Bagley, C. M.: Ruptured diverticulum of the jejunum, 691
Baker, George S., and Chenault, Harvey: Compound, comminuted fractures of the skull in battle casualties, 560
Barker, Nelson W.: Anticoagulant therapy in postoperative thrombophlebitis and pulmonary embolism, 778
Barker, Nelson W., Hines, Edgar A., Jr., and Kvale, Walter F.: The treatment of acute arterial occlusion of the extremities with special reference to anticoagulant therapy, 250
Barnes, Arlie R.: Coronary heart disease: prognosis and life adaptation, 886
Bedside diagnosis of liver disease, The, 133
Bell, E. T., Bittner, J. J., Dennis, C., O'Brien, W. A., Treloar, A. E., Visscher, M. B., and Oliver, C. P.: Relationship between pregnancies and age of occurrence of breast cancer in the human, 1230
Benign strictures of the extrahepatic bile ducts at the University of Minnesota Hospitals, 823
Benjamin, E. G.: Obstructive jaundice, 818
Berger, Alex G.: Poliomyelitis, 761
Bergh, George S.: Volvulus of the stomach, 1050
Bile ducts, extrahepatic, Benign strictures of the, at the University of Minnesota Hospitals, 823
Bittner, J. J., Dennis, C., O'Brien, W. A., Treloar, A. E., Visscher, M. B., Oliver, C. P., and Bell, E. T.: Relationship between pregnancies and age of occurrence of breast cancer in the human, 1230
Bleeding from the rectum, The significance of, 274
Blood dyscrasia with and without associated "atypical lichen planus," 575
Blood groups and types, The practical application of new developments in, 1132
Blood plasma transfusions, Reactions following, 1209
Blumenthal, J. S.: Ethylene disulphonate in allergy, 690
Bone production, The acceleration of, by use of ground bone, 328
Borg, Joseph F.: Bacillary dysentery, 1108
Bosma, J. F., Moss, A. J., and Merner, T. B.: Cystic fibrosis of the pancreas, 429
Boyd, W. L.: Progress in the control of brucellosis (Bang's disease) in domestic animals, 681
Breast, Hormonal dyscrasias of the, 695
Breech presentation in private practice, The management and end results in forty-five cases of, 457
Brief survey of prostatic surgery, A, 995
Briggs, John Francis: Penicillin, 1215
Bronchiectasis, Surgical treatment of, 898
Brown, Philip W., and Gillespie, D. R.: Blood dyscrasia with and without associated "atypical lichen planus," 575
Brucellosis (Bang's disease), Progress in the control of, in domestic animals, 681
Brucellosis—clinical aspects, 679
Bundle branch block, Effect of antiluetic therapy on (case report), 582
Burt, Georgie M., Spink, Wesley W., Hall, Wendell H., and Alden, John: The treatment of pneumococcic and staphylococcic meningitis with penicillin and sulfonamides, 553
Bushard, W. J.: Intra-ocular malignant melanomas of the choroid, 1005
Butler, J. K., Wells, Arthur H., and Joffe, Harold H.: Diagnostic case report (periarteritis nodosa, hypertensive cardiovascular renal disease), 905

Book Reviews

Archer, Vincent W.: The osseous system, 189
Bell, E. T.: Renal disease, 732
Caffey, John: Pediatric x-ray diagnosis, 94
Cullen, Stuart C.: Anesthesia in general practice, 957
Fishbein, Morris (editor): Doctors at war, 189
Fulton, John F., and Stanton, Madeline E.: The centennial of surgical anesthesia—an annotated catalogue, 1282
Health Education Council: Charter of suggested school policies, 94
Hennessy, Thomas Francis: Vocational and professional monograph, 845
MacKenzie, Dewitt: Men without guns, 189
Marihuana problem in the City of New York, 733

70369

Morton, W. T. G.: A memoir to the Academy of Science at Paris of a new use of sulphuric ether (1847), 1282
Patten, Bradley M.: Human embryology, 1069
Robinson, Victor: Victory over pain, 1282
Te Linde, Richard W.: Operative gynecology, 1283
Thewlis, Malford W.: The care of the aged, 389
Titus, Paul: The management of obstetric difficulties, 637
Wiener, Meyer (editor): Ophthalmology in the war years, 1283
Wilmer, Harry A.: Corky, the killer, 732

C

Calculation of disability in the extremities, 160
Callahan, Francis F., and Sanderson, Anton G.: Intrapleural penicillin therapy in tuberculosis and mixed infection empyema, 1008
Calyceal diverticulum, 578
Campbell, Orwood Jackson: The relationship between general practitioner and specialist, 1233
Cancer, breast, in the human, Relationship between pregnancies and age of occurrence of, 1230
Cancer detection centers and allied cancer projects, 269
Cancers of the rectosigmoid and upper rectum, A modified Halsted bulkhead rectal anastomosis for use in resection of, 1051
Carcinoma, Virus aspects of, 277
Cataract extraction under sodium pentothal, 700
Centenary of the demonstration of ether anesthesia, The, 993
Cerebral palsy, The effect of prostigmin in, 419
Chenault, Harvey, and Baker, George S.: Compound, comminuted fractures of the skull in battle casualties, 560
Chloride, myristyl-gamma-picolinium; The use of, in surgery, 321
Cholecystectomy, 819
Cholecystectomy: Its origin and present status, 313
Choroid, Intra-ocular malignant melanomas of the, 1005
Collins, Arthur N.: Malignant tumors of the kidney, 332
Colon, Acute non-malignant perforations of the, 935
Compound, comminuted fractures of the skull in battle casualties, 560
Cook, Edward N., and Irmisch, George W.: Double and accessory urethra, 999
Cook, Edward N., and Rives, Hugh F.: Ureteral obstruction caused by aneurysm of the iliac artery, 143
Coronary emergency, The treatment of the, 890
Coronary heart disease: prognosis and life adaptation, 886
Coronary heart disease—the occupational disease of doctors, 881
Creevy, C. D.: A brief survey of prostatic surgery, 995
Cystic fibrosis of the pancreas, 429
Cytology of the erythrogenic reticulum of the bone marrow in pernicious anemia before and after administering folic acid, The, 1212

Clinical-Pathological Conferences

Air embolism, 1238
Calyceal diverticulum, 578
Chronic intradural hematoma, 258
Diffuse myxoma of lower extremity with elephantiasis, 1017
Diphtheria; A report of six deaths, 335
Hormonal dyscrasias of the breast, 695
Meningioma of the spinal cord, coronary sclerosis with myocardial infarction, congestive heart failure, 1241
Normal appendices in 1,000 appendectomies, 1019
Periarteritis nodosa, hypertensive cardiovascular renal disease, 905
Practical application of new developments in blood groups and types, The, 1132
Pulmonary emphysema, 441
Spontaneous perforation of esophagus, 442
Subacute bacterial endocarditis with rupture of spleen, 791
Superior pulmonary sulcus tumor, 1134

Communications

Brown, George E., Jr., 76

D

Dachau, Medical experiences at, 46
Daugherty, Guy W., Baggenstoss, Archie H., and Keith, Norman M.: Atypical chronic glomerulonephritis, 1218
Davis, Graham L.: Planning the hospital for community service, 1112
Deliveries, term, Neonatal deaths following, 1937-1945, 783
Dennis, Clarence: A modified Halsted bulkhead rectal anastomosis for use in resection of cancers of the rectosigmoid and upper rectum, 1051
Dennis, C., O'Brien, W. A., Treloar, A. E., Visscher, M. B., Oliver, C. P., Bell, E. T., and Bittner, J. J.: Relationship between pregnancies and age of occurrence of breast cancer in the human, 1230
Development of a program of health service in industry, 1012

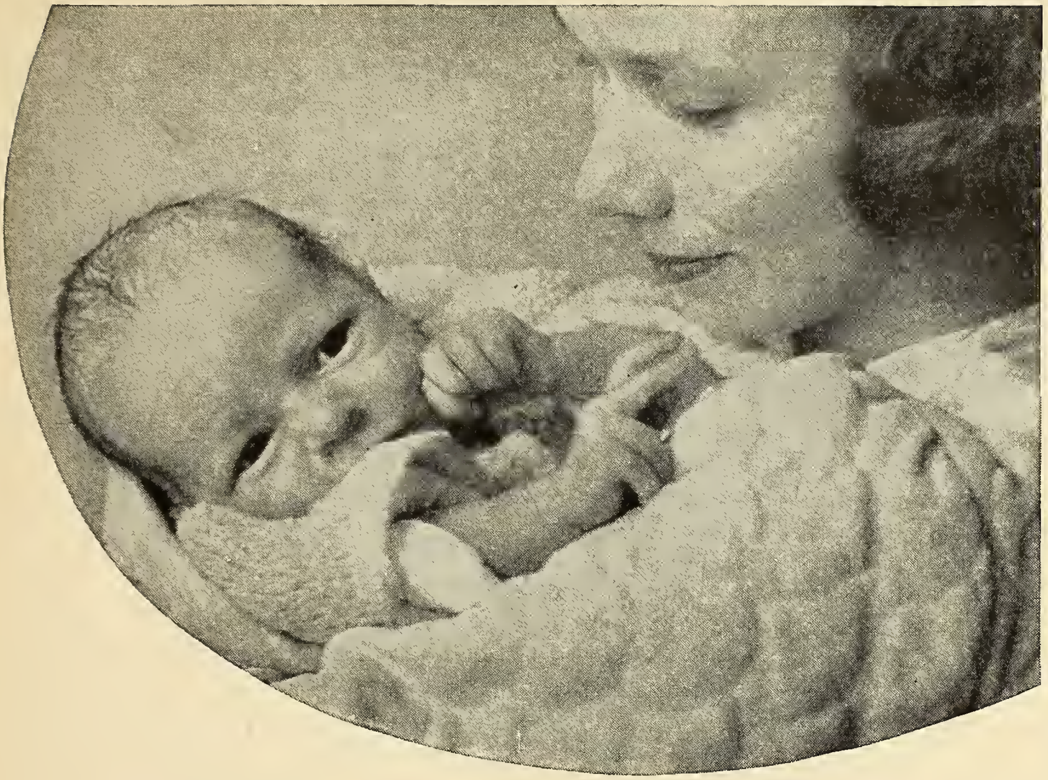
Equipment of Recognized Merit



You'd think he was 70

With his "fussy" appetite, intestinal upsets and restless sleep, you'd think he was 70 years instead of 7 weeks old. A change to 'Dexin' brand High Dextrin Carbohydrate formulas often helps restore a normal, healthy appetite, and sound, undisturbed sleep. The high dextrin content of 'Dexin' (1) diminishes intestinal fermentation and the tendency to colic and diarrhea, and (2) promotes the formation of soft, flocculent, easily digested curds.

'Dexin' provides formulas that are well taken and retained. Palatable and not too sweet, 'Dexin' is soluble in hot or cold milk or other bland foods. 'Dexin' does make a difference.

'Dexin' Reg. Trademark

'Dexin'

HIGH DEXTRIN CARBOHYDRATE

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

CAMEL CIGARETTES

Medical Relations Division

ONE PERSHING SQUARE
NEW YORK 17, N.Y.

Dear Doctor:

You may recall having been asked the question: "What cigarette do you yourself smoke, Doctor?"

In the past few months every physician in private practice in the United States has been asked that same question...asked solely and clearly on the basis of personal preference as a smoker.

Three nationally known independent research groups did the asking in what we believe is one of the most impartial and most comprehensive surveys of physician preference ever conducted.

You may or may not be a cigarette smoker, but we believe you will be interested not only in the results of these surveys, but in the methods by which these results were obtained.

Yours very truly,

A. G. Clarke.

A. G. Clarke
Director
Medical Relations Division

CALEDONIA 5-1910

A physician asked us the question first—

A smoker himself, he asked: "What cigarette do most doctors smoke?"

We know that many physicians smoke, that many of them prefer Camels; but we couldn't answer the doctor's query.

We turned the question over to three nationally known independent survey groups. For months these three groups worked . . . separately . . . each one employing the latest scientific fact-finding methods.

This was no mere "feeling the pulse" poll. No mere study of "trends." This was a nationwide survey to discover the actual fact . . . and from the statements of physicians themselves.

> *To the best of our knowledge and belief, every physician in private practice in the United States was asked: "What cigarette do you smoke?"*

The findings, based on the statements of thousands and thousands of physicians, were checked and re-checked.

ACCORDING TO THIS RECENT NATIONWIDE SURVEY:

More doctors smoke Camels than any other cigarette

CAMEL
CAMEL
TURKISH & DOMESTIC BLEND CIGARETTES
CHOICE QUALITY

And by a very convincing margin!

Naturally, as the makers of Camels, we are gratified to learn of this preference. We know that no one is more deserving of a few moments to himself than the busy physician . . . of a few moments of relaxation with a cigarette if he likes. And we are glad to know that so many more physicians find in Camels the same added smoking pleasure that has made Camels such an outstanding favorite among *all* smokers.

at home, in
your own country

To those of you who left your homes to serve your country we extend a warm and friendly welcome, a happy welcome home. The extraordinary service the medical profession gave in the war can't be told here. Here we want to say how glad we are to have you back again, away from the heavy change of war; back into your proper sphere, back again into your peace-time practice, back to a long, peaceful, happy service in the nation's health. ▸ ▸ ▸ Back again at home, in your own country.

Dietary Protein after Surgery and Other Trauma

apparently must be maintained at a level above normal in order to assure proper wound healing* and at least average resistance against infection.** The feeding of meat, therefore, in adequate amounts, as soon as it can be instituted, appears doubly advantageous: the protein content of meat is high and of highest biologic value; the human digestive tract appears well adapted for handling meat protein.**

*" . . . in a variety of medical and surgical conditions there may occur a considerable depletion of body protein owing to a combination of factors, of which the two most important are a generally diminished protein intake and an enhanced protein catabolism. This situation inhibits wound healing, renders the liver more liable to toxic damage, impedes the regeneration of hemoglobin, prevents the resumption of normal gastrointestinal activity and delays the full return of muscular strength. It is obvious that to meet the situation an adequate supply of proteins and calories must be made available to the body. . . . This implies at least 150 Gm. of protein and 3500 calories, with as much as 500 Gm. of protein daily when trauma has been severe, as in serious burns." (HOFF, H. E.: Physiology, New England J. of Med. 231:492 [Oct. 5] 1944.)

**"Cannon . . . cites the evidence which indicates that diminished protein intake lowers resistance to infectious disease, and corroborates it by his own experiments . . . it seems probable that the small intestine is better adapted for handling protein (especially meat protein) than for other types of food. . . . it is especially well supplied with enzymes which attack protein, and the digestion of meat has been shown to be more complete than that of foods of vegetable origins." (CRANDALL, L. A., Jr.: The Clinical Significance of the Plasma Proteins, Memphis M.J. XIX:147 [Oct.] 1944.)

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

White's
COD LIVER
OIL
CONCENTRATE

WHOLLY NATURAL SOURCE

LOW COST PER DAY

WELL TOLERATED

These are advantages which, for many years, have fixed White's Cod Liver Oil Concentrate in the minds of physicians everywhere as their first thought in prescribing.

TO THESE ADVANTAGES ADD *economy*

Cost to the patient has *not* increased. Average "infant antirachitic" prophylactic dosage costs *still* less than a penny a day.

Three palatable, convenient dosage forms — LIQUID (for drop dosage to infants), TABLETS AND CAPSULES.

Ethically promoted — not advertised to the laity.

The Preference is Overwhelming

A comprehensive report published in *Human Fertility*[1] shows an overwhelming preference by experienced clinicians for the "Diaphragm and Jelly" method of conception control.

The report covering 36,955 new cases shows that the diaphragm and jelly method was prescribed for 34,314, or 93%.

On the evidence supplied by competent clinicians we continue to suggest that for the optimum in protection the physician should prescribe the combined use of a vaginal diaphragm and spermatocidal jelly.

When you specify "RAMSES"* a product of highest quality is assured.

WHEN FORMULAS MUST BE "TAILORED TO FIT"

"WELL, DOCTOR, I'D PUT THIS BABY ON DRYCO"

"His condition requires careful dietary supervision—with Dryco you can easily adjust the formula to meet his requirements."

Because Dryco offers the physician wide limits of formula flexibility, it is ideally suited to *special* feeding . . . besides being perfectly suited to *normal* cases. It may be prescribed with or without added carbohydrate . . . and may be employed in *concentrated* form also when indicated.

The high-protein, low-fat ratio of Dryco (2.7 to 1) assures optimum protein intake and minimal gastro-intestinal upsets from fat indigestion. In addition, Dryco contains adequate vitamins A, B_1, B_2, and D, plus essential milk minerals.

Formulac

for adequate infant nutrition

FORMULAC, newly introduced on the market, is the trade name for a fortified infant food which makes supplementary vitamin administration unnecessary.

FORMULAC (a reduced milk in liquid form) was developed by E. V. McCollum. It is sufficiently supplemented with vitamins and minerals to render it an adequate food for babies. Incorporation of the vitamins *into the milk itself* eliminates the risk of maternal error or carelessness.

FORMULAC presents a flexible basis for formula preparation. Supplemented by carbohydrates at your discretion, it may readily be adjusted to fit each individual child's needs.

FORMULAC has been tested clinically, and found satisfactory in promoting infant growth and development.

FORMULAC is inexpensive—within price range of even low income groups. It is on sale at most grocery and drug stores.

FORMULAC IS PROMOTED ETHICALLY

For professional samples and further information about this new infant food, mail a card to National Dairy Products Company, Inc., 230 Park Avenue, New York 17, N. Y.

In the City of Bagdad lived Hakeem, the Wise One, and many people went to him for counsel, which he gave freely to all, asking nothing in return.

There came to him a young man, who had spent much but got little, and said: "Tell me, Wise One, what shall I do to receive the most for that which I spend?"

Hakeem answered: "A thing that is bought or sold has no value unless it contains that which cannot be bought or sold. Look for the Priceless Ingredient."

"But what is this Priceless Ingredient?" asked the young man.

Spoke then the Wise One: "My son, the Priceless Ingredient of every product in the marketplace is the Honor and Integrity of him who makes it. Consider his name before you buy."

In the Pneumonias

DURING the recent past, numerous investigations have shown that penicillin is the treatment of choice in the pneumonias (pneumococcic, streptococcic, staphylococcic).* Penicillin is virtually nontoxic, even in the massive dosages at times required. Its efficacy apparently is the same against sulfonamide-resistant and nonresistant organisms of the groups named. Even in advanced stages of the disease, in the presence of serious complications, penicillin usually proves a life-saving measure.

Since penicillin has become available in quantities that may well be adequate for all needs, it merits being the physician's first thought with every pneumonia patient.

PENICILLIN-C. S. C.

Penicillin-C.S.C. deserves the physician's preference not only in the pneumonias, but whenever penicillin therapy is indicated. Rigid laboratory control in its manufacture, and bacteriologic and biologic assays, safeguard its potency, sterility, nontoxicity, and freedom from pyrogens. The state of purification reached in Penicillin-C.S.C. is indicated by the notably small amount of substance required to present 100,000 Oxford Units. Because of this purity, incidence of the undesirable reactions, attributed by many investigators to inadequate purification, is greatly reduced.

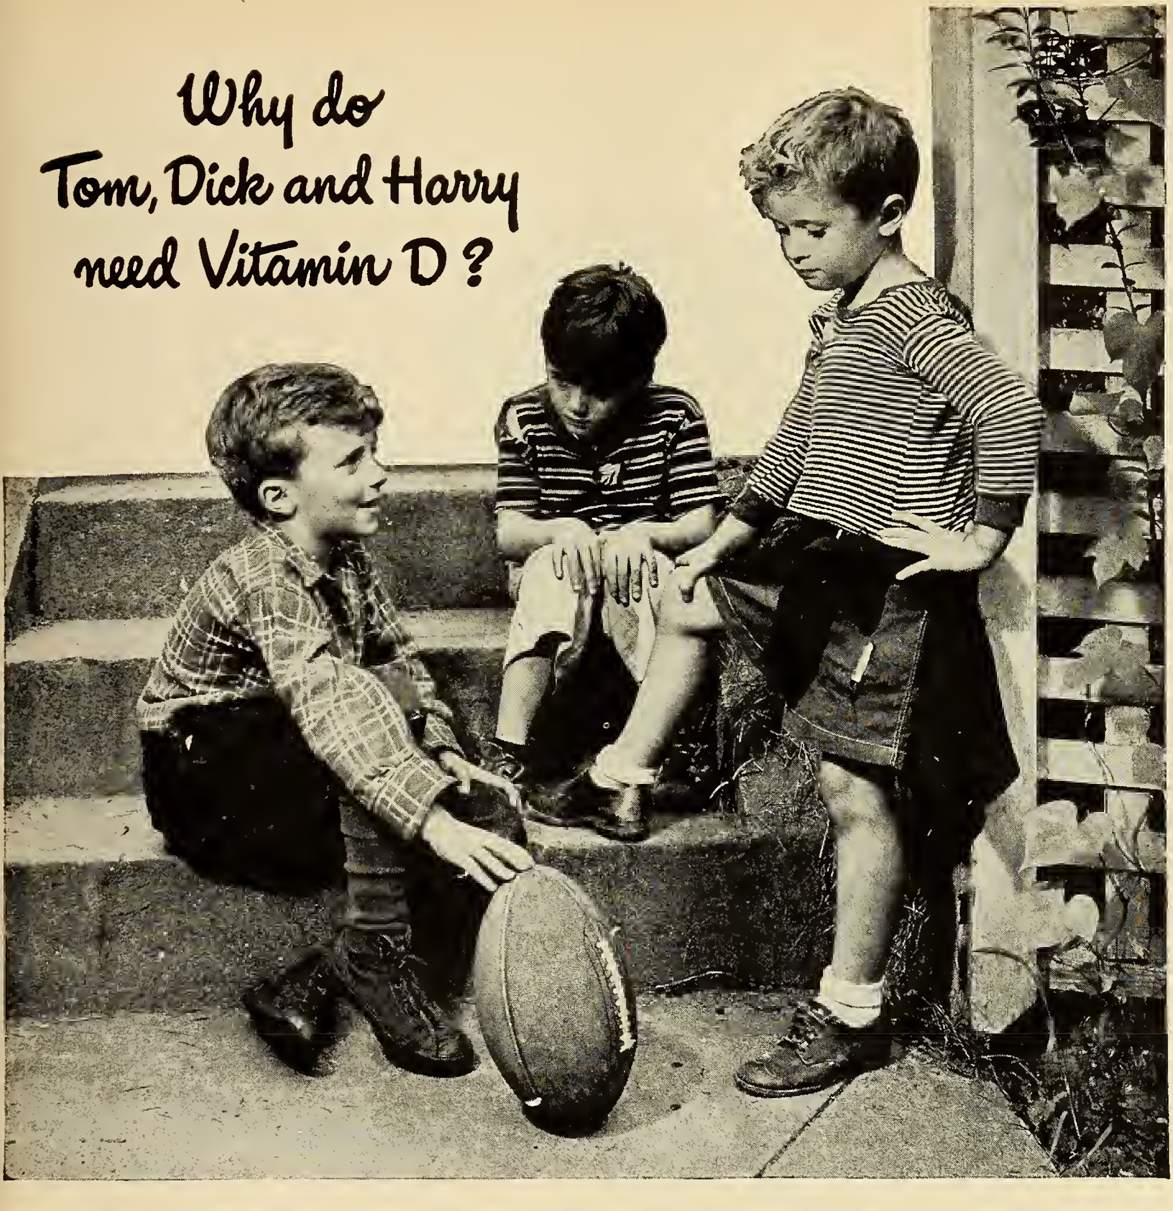
Why do Tom, Dick and Harry need Vitamin D?



Growing children require vitamin D mainly to prevent rickets. They also need vitamin D, though to a lesser degree, to insure optimal development of muscles and other soft tissues containing considerable amounts of phosphorus . . . Milk is the logical menstruum for administering vitamin D to growing children, as well as to infants, pregnant women and lactating mothers. This suggests the use of Drisdol in Propylene Glycol, which diffuses uniformly in milk, fruit juices and other fluids.

ARMOR AND ARMAMENTARIUM

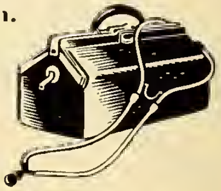
Guns are silent and grass grows in the foxholes, but there can be no peace treaty in the endless war on mankind's immortal enemy—Disease. Home comes the physician from his lifesaving on the battlefields of man-made death abroad to march again beside his colleagues who have so valiantly held the casemates of health at home.

Battle front and home front, boulevard and dirt road, the mighty facilities of the medical center and the challenge of practice in the lonely farmhouse—all are the front line trenches in humanity's continuing crusade to tame cannibal protoplasm. There is no discharge in that war.

The first cry of pain in the world was the first call for a physician. It has been answered as it echoed down the centuries; it will be answered in the unrolling years of the future.

As this questioning year of 1946 opens with the world convalescing from malignant political disease, we would like to claim the privilege of welcoming the thousands of physicians returning from unparalleled service on war fronts—of saluting those who shouldered such heavy burdens at home—of expressing the confidence that the traditional unity of the profession armed with new and potent weapons will drive the front lines of the war on disease ever forward.

We know that we are joined in this expression by all organizations which seek to play their roles, large and humble, as institutions of supply to those "bound by the covenant and oath, according to the law of medicine." S. H. Camp and Company, Jackson, Mich.



In Estrogenic Therapy TOLERANCE

One of the important advantages of "Premarin" lies in the fact that it is exceptionally well tolerated. Although highly potent, "Premarin" rarely produces unpleasant side effects—a statement which finds ample corroboration in the extensive bibliography. In "Premarin" the physician will find a medium for estrogenic therapy which is noted for its therapeutic effectiveness. "Premarin" is derived exclusively from natural sources and its administration is usually followed by what is invariably described by the patient as a general feeling of well-being.

Let your HEAD take you

(The average American today has a choice of just going where "his feet take him", or choosing wisely the course to follow. Let's skip ahead 10 years, and take a look at John Jones—and listen to him . . .)

"Sometimes I feel so good it almost scares me.

"This house—I wouldn't swap a shingle off its roof for any other house on earth. This little valley, with the pond down in the hollow at the back, is the spot I like best in all the world.

"And they're mine. I own 'em. Nobody can take 'em away from me.

"I've got a little money coming in, regularly. Not much—but enough. And I tell you, when you can go to bed every night with nothing on your mind except the fun you're going to have tomorrow—that's as near Heaven as man gets on this earth!

"It wasn't always so.

"Back in '46—that was right after the war and sometimes the going wasn't too easy—I needed cash. Taxes were tough, and then Ellen got sick. Like almost everybody else, I was buying Bonds through the Payroll Plan—and I figured on cashing some of them in. But sick as she was, it was Ellen who talked me out of it.

"'Don't do it, John!' she said. '*Please* don't! For the first time in our lives, we're really saving money. It's *wonderful* to know that every single payday we have *more* money put aside! John, if we can only keep up this saving, think what it can mean! Maybe someday you won't have to work. Maybe we can own a home. And oh, how good it would feel to know that we need never worry about money when we're old!'

"Well, even after she got better, I stayed away from the weekly poker game—quit dropping a little cash at the hot spots now and then—gave up some of the things a man feels he has a right to. We didn't have as much fun for a while but we paid our taxes and the doctor and—we didn't touch the Bonds.

"What's more, we kept right on putting our extra cash into U. S. Savings Bonds. And the pay-off is making the world a pretty swell place today!"

MINNESOTA MEDICINE

IN THE SHORTENING OF *Convalescence*

More than so-termed tonics and restoratives, Ovaltine can be of material aid in shortening the period required for the return of strength and vigor following recovery from infectious or prolonged illnesses. During the acute stages of febrile diseases, when the patient's nutritional intake is low, while requirements are higher than normal, many metabolic deficits are developed. These can be made good only by a high intake of essential nutrients during the recovery period, for only after these nutritional deficits are wiped out can former strength and well-being return.

Ovaltine offers many advantages as a nutritional supplement to the diet of convalescence. This delicious food drink is rich in needed minerals, vitamins, and biologically adequate proteins. Its appealing taste invites consumption of three or more glassfuls daily. Its notably low curd tension encourages rapid gastric emptying, an important factor in maintaining good appetite.

the healing power of sleep

Adequate rest is an important factor in the successful treatment of upper respiratory infections. Frequently, nasal congestion keeps the patient irritable and sleepless. Solution 'Tuamine Sulfate' (2-Aminoheptane Sulfate, Lilly), administered by spray or dropper, quickly shrinks the nasal mucosa, permitting easy, natural breathing. There is no secondary engorgement or central-nervous-system stimulation. Specify Solution 'Tuamine Sulfate,' 1 percent, for home use. The 2 percent solution is recommended for office procedures in which maximum shrinkage is required.

WHAT PUBLIC HEALTH EXPECTS OF THE PRIVATE PHYSICIAN

HAVEN EMERSON, M.D.
Professorial Lecturer in the School of Public Health
University of Minnesota
Minneapolis, Minnesota

THE first three lectures to commemorate the leadership and inspiration of Dr. John W. Bell in the tuberculosis campaign of Hennepin County were devoted to topics so nearly akin to what you have assigned to me today, that I fear some inevitable repetition of fact or of opinion. However, since man's experience with tuberculosis has been longer than his acquaintance with either the art or science of medicine, some reiteration of ancient truths may be excused. Permit me to develop the topic in hand in part historically and further by reference to the formal requirements of contemporary sanitary law and to the current experience of your own community.

The first epidemiologist Hieronymus Fracastorius gave in his classical volume De Contagione in 1546 the first clear description of the contagion of consumption. Without the ability to see or identify the tubercle bacillus he coined the expression "seminaria of disease" and wrote "These seeds are the carriers of the contagion and that they are the first origin of the disease there can be no doubt. It may be considered that the force of the disease lies in these seeds since they have the power to propagate and reproduce their own kind."

This wise and philosophical student of the mass manifestations of communicable diseases, wasted no time on environmental, economic, social or racial factors. He found a disease of universal prevalence, the spread and continuity of which he knew to be due to the infection of the well by the sick, and he declared with a convincing simplicity that the need was "to combat germs and prevent contagion."

Down the ages this eternal truth has resounded, and those whose ears have been deaf, whom ignorance and selfishness have made blind, whose reasoning has lacked logic, have paid the penalty of sickness and death in their time.

Leaping the four centuries from Fracastorius to Frost, from Verona to Baltimore, from the era of Italian renaissance to the first fruiting of systematic epidemiology in our own country, we read the brief statements of the two conditions which limit the propagation of the tubercle bacillus: (1) "In order to escape from its host it must cause a lesion which breaks through to the surface—in general an extensive lesion which severely damages the host; (2) it succeeds in producing such lesions in only a limited proportion of infected persons."

"Other human pathogens may be subject to one or the other of these conditions but not to both."

"The combination of these two limiting conditions is the peculiarity of the tubercle bacillus which makes it more amenable to control by case isolation than are such diseases as diphtheria, scarlet fever or measles."

If we may define public health services as the application of the sciences of preventive medicine by public authority for social benefit, then the

---

The John W. Bell Tuberculosis Lecture delivered before the Hennepin County Medical Society, December 3, 1945.

private physician must be expected to discover the infected person, identify him by name and address to public authority, and aid in revealing the source of infection in this index case and the tracing of secondary or associated infected persons among contacts.

To follow the implications of Frost's two premises, it is only the sputum-positive cases that need to be isolated in order to prevent the spread of infection, but all clinically recognizable infected persons should be known to the health department. Furthermore, and to make our task the easier, for the eventual eradication of human tuberculosis, it requires only that the rate of transmission be held permanently below that required to carry on the succession.

If from year to year and generation to generation there is a reduction in the number of infectious hosts, the end must be extermination of the tubercle bacillus. If we but keep the present balance of a diminishing number of sources of infection, human tuberculosis will disappear. With the practical or near approach to eradication of bovine tuberculosis among dairy cattle, the infected open or positive sputum case of human tuberculosis is the only source of infection in the United States today.

In France and in most of Continental Europe there is little confidence in ultimate eradication of tuberculosis. Their experience with wars and hunger have dulled their imagination and postponed a vision of the future which to us seems vivid and near. The Frenchman clings to the philosophy of Calmette which presupposes universal exposure to the tubercle bacillus and therefore calls for universal artificial immunization.

Our experience leads us to the contrary conclusion, that tuberculosis is in the process of disappearance which can be awaited with confidence while persisting in our efforts to separate the sick from the well and reduce progressively the number of positive sputum patients at large among us.

As the moderate inoffensive alcoholic habitué is the reservoir from which the chronic alcoholic and inebriate mental derelicts are recruited, so it is the infected persons revealing no subjective or objective evidence of active pulmonary tuberculosis from whom are developed the active, progressive positive sputum patients who constitute the links in an age-old chain of infection. For administrative justice to all the people and for competent scientific epidemiology of the disease by the health department, all cases of appreciable clinical tuberculosis of any part of the body must be reported whether or not at the time the tubercle bacillus has been found in the body discharges.

As in the administrative control of typhoid fever we have passed through several evolutionary phases of method, from the general to the particular, from the broad programs of water purification, sanitary sewage disposal, and pasteurization of milk to the meticulous detective search for the carrier and the supervision of his way of life, so have we moved from popularization of personal hygiene, from mass information, to a point where nothing short of universal x-ray diagnosis will suffice for control of tuberculosis.

What shall be our immediate and future program directed not towards a remote and indefinite objective, but geared and adapted to reach a terminal point, now obviously within our reach? We must gird ourselves for the last lap, the crowning competition and reward among the states, between cities, counties and ultimately between nations. Already we see in your own state and as well in rural districts and in large cities, cases of optimum health, areas and communities among which no death from tuberculosis has occurred over a five-year period, broad population units from which the young people coming to your great University are free from tuberculous infection.

The challenge ahead is stirring. Will you let Utah, Idaho or Washington claim the distinction of being the first state without a death or a new case of clinically active tuberculosis reported within a year or a quinquennium?

It was with a distinct emotional thrill, a sense of lift and elation, that I visited recently a county of the southern tier where annual death rates from tuberculosis had averaged about 5 per hundred thousand per annum. And it was with no less interest and concern that I found a northern county so effectively busy with case finding that within two years it may be expected that every person, old and young, will have had a permanent x-ray record of the chest.

To shape our program to a certain and successful conclusion we must discard traditional generalities. Of course, we shall be concerned with nutrition, housing, working environment, length of work days, economic justice, recreational facilities, and rehabilitation of the post sanatorium patient. These are but the expressions of an enlightened humanism but no one or all of these will materially affect the incidence of tuberculous infection or manifest tuberculous disease.

To be definite and specific we must use as direct methods as we would for smallpox or typhoid fever, granting that social assistance is worthy of support, but not at the cost of overlooking the primary role of the spreader.

All control of communicable disease begins with prompt information as to the occurrence of the disease in question in a certain person at a certain address. Verification of the diagnosis may be needed. Search for prior and subsequent cases among contacts must be prompt and complete. Each person capable of infecting others must be so controlled as to be no hazard in the community, preferably by being admitted to a tuberculosis hospital. Since tuberculosis is commonly a silent and insidious invader, reliance upon complaint of illness by the patient or diagnosis without x-ray of the chest cannot be longer tolerated. I must refrain from further repetition of such truisms long well known to official and voluntary agencies. Let me but say that nowhere is the modern program against tuberculosis better expressed than in that brief and authoritative little handbook by Henry D. Chadwick and Alton S. Pope, "The Modern Attack on Tuberculosis," obtainable for a dollar from the Commonwealth Fund. In order of importance are:

1. Isolation in sanatoria of all known open cases of pulmonary tuberculosis.
2. Good medical care preferably in institutions of known active, though not at present open, cases.
3. Systematic search for early and unrecognized cases and their isolation if discharging tubercle bacilli.
4. Social and medical protection of underprivileged groups who are endangered by tuberculosis by reason of ignorance, poverty, unemployment, hazardous occupations and crowded conditions of living.

As fewer cases are reported and discovered, open positive-sputum patients must be the main objects of control, by increasingly effective measures at home and in sanatoria.

To quote Frost again:

"As the disease becomes rarer, less a matter of everyday experience, we may be assured that public opinion will not only support but will even demand more rigid isolation."

How does this proposal for specific practical measures compare with today's performance?

One can only marvel at the favorable picture of falling mortality and reported incidence of tuberculosis in Minnesota and Hennepin County in the light of the record of reporting.

In the state of Minnesota in the period 1910 to 1940 when the tuberculosis death rate fell from 109.4 to 29.7, the percentage of deaths not previously reported as cases of the disease fell from 86 to 15.5 per cent.

It is probable that less than half of the active cases of tuberculosis have been known to the authorities at any time in the past thirty years or are today so known.

To quote from the 1922-43 report of the Minnesota State Board of Health, "In 1910 there were more than three times as many deaths from tuberculosis as there were reported cases. Tuberculosis is a reportable disease, but it has never been adequately reported."

Michigan today leads all the states in the ratio of new cases of tuberculosis reported in a year to deaths from this disease in the same period, 3.25, and yet evidence is abundant that not less than five and probably between seven and ten cases could be discovered and should be reported if the private and public resources of medicine were used to full advantage.

The citizen may well ask why! Is a requirement of the Board of Health, having the force and effect of a law, to be disregarded with impunity, and if so, who enjoys the privilege of this violation of the spirit and intent of the law? May I respond to the title of my discussion by saying that the humblest expectation of public health is that physicians recognize tuberculosis prior to the patient's death and report every person infected and receiving medical care, whether or not such patients are at the time discharging tubercle bacilli.

And now for the city of Minneapolis. In the year 1919, 16 per cent of cases of tuberculosis reported to the Division of Public Health, were reported less than one month prior to death or actually after death by declaration on the death certificate. Twenty-five years later, in 1944, 5.8 per cent of reported tuberculosis was reported within a month of death or after death, a substantial improvement. This is not, however, a creditable record and must be explained by the medical profession. Permit me to suggest now that the Hennepin County Medical Society appoint a permanent committee on tuberculosis, to which should be referred by the Division of Health, for inquiry and periodical report to the membership of the society, each instance of a report of tuberculosis made either within a month of death or only by the death certificate.

In making special study of similar situations in Philadelphia and Boston I found in the latter city that by fifty cases of chronic pulmonary tuberculosis with intermittent positive sputum not reported until within a month of death, there had been, over a period prior to the reports of these patients to the health department, 1,500 person years of exposure of intimate household or family contacts, or an average of thirty person years of exposure per case of tuberculosis, or six persons exposed for as long as five years each, to a patient lacking any semblance of sanitary control at home and living out the years of his disease without any sense of obligation to avoid infecting others.

Until the practicing physician reports all cases of tuberculosis whether open or closed, positive or negative sputum, to the Division of Health at once on making provisional or suspected diagnosis we shall not be in a position to give the community, the family, the fellow workmen, a protection they are entitled to.

This city has an enviable record of progress in abatement of tuberculosis revealed in an almost uninterrupted fall in the resident death rate from this dease from 222.5 per 100,000 of population in 1889 to 30.4 in the year 1944. Mathematical calculations suggest that, in a disease spread by a chronic carrier and from no other source, the final stages of reduction to entire disappearance should be at a more rapid rate than when the disease is widely prevalent. Chadwick and Pope suggest a probable death rate from tuberculosis in 1980 of ten and a possible disappearance from the list of causes of death by the end of this century. The right answer is anybody's guess, but of one thing we can be certain — any slowing in the rate of regression in the next few decades will be due to professional and civic indifference and not to any lack of the basic facts or of wise guidance as to policies, methods and tests of performance.

The physician in private practice is not only the trustee of the science of human biology, and the sole representative of society licensed to deal responsibly before the law with life and death, but he is the medical conscience of the community. Upon his precise, prompt, wholehearted co-operation, the entire structure of modern public health depends. If in a mistaken spirit of economic self-protection or in the expectation of financial betterment he opposes publicly adopted policies of disease prevention and control within the framework of sanitary law, he destroys in large measure his own professional prestige and draws down upon himself the threat of that most undesirable proposal of social utopians, a compulsory and state-supported practice of medicine, than which I can conceive no worse blow to medical and social progress in our nation.

It has come to my attention here as in other cities where I have made studies of public health services that some physicians and even specialists in tuberculosis consider that apparently healed so-called reinfection type tuberculosis is of no concern to public authority and they accept no obligation to report such patients. This is a mischievous and obstructive practice as it prevents both epidemiological and administrative services indispensable to the proper functioning of a registry and control system.

I find to my surprise a sharp distinction between the attitude of the medical profession here and that in my home town. Any person in New York, regardless of economic status, is welcomed at a tuberculosis diagnostic clinic of the Departments of Hospitals and Health. If the patient has or can obviously afford the services of a private physician, or has been referred for diagnostic consultation to the tuberculosis clinic by his own physician, the record and diagnostic opinion is reported to the family physician. The accuracy, competence, economy of the standard x-ray and personal diagnostic service for the control of this communicable disease are of such a kind as to contribute to, not detract from, the services of the private practitioner.

No private sources could have offered the 500,000 x-rays of the chest as part of the continuing screening process of recent years in New York City. The radiologist and the internist and the tuberculosis specialist have gained, not lost, by the widespread concern with unsuspected pulmonary disease revealed by x-rays of presumably healthy persons.

From a beginning in 1900 when practically all the patients coming to the first tuberculosis clinics were cases of advanced disease there has been an increasing proportion of all clinic patients found to have no tuberculous disease until now almost

80 per cent of the clinic clientele is found to be non-tuberculous.

Certainly it is contrary to good public policy, against the interest of patients and of the local medical profession that a tax-supported diagnostic service for tuberculosis should be denied to any person, employer or employe, mistress or maid, rich or poor, for the reason that many such persons could afford the consultation and x-ray fee of the private practitioner. People should be encouraged to come to such free tuberculosis diagnostic clinics, and their physician of choice or preference should receive the report of the clinics' findings.

The free chest x-ray to establish or exclude the diagnosis of pulmonary tuberculosis appears to me to be as much a right of the citizen as it is a duty of civil government to offer, and entirely comparable to, the blood serology offered by the diagnostic laboratory of the state or local department of health to identify cases of syphilis.

If under such ideal conditions of organization as have already been proved practicable, a miniature x-ray of the chest and a blood test for syphilis can be provided by public authority for little more than twenty-five cents per person, obstruction against the widespread, not to say universal, use of such tests by the public would bring nothing but discredit upon the medical profession.

Among the factors leading to delay in reporting of cases of tuberculosis by the private practitioner is the inclination of some physicians to spare the feelings of patient and family by not declaring the actual diagnosis and then by attempting to continue a regime of care of the patient at home as long as the family can continue to pay for his services. I am not at the moment concerned with the ethical weakness of the physician's position in such cases, but solely with the effect upon the origin and spread of the infection in the community.

Home care of the tuberculous is of course possible but except under relatively rare conditions whether for the well to do or for the wage earner, it is a distinctly second-best choice from the point of view of therapy and permits almost inevitable transmission of infection to household contacts.

When we recall the high probability of infection of nurses under even rigid hospital discipline and with excellent equipment and management in sanatoria, we cannot doubt the higher probability of such infection in home care of the tuberculous.

An instance of misfortune due to failure of a plant physician to report a case of tuberculosis in a young woman applicant for employment came to my attention as illustrative of indifference on the part of an occasional physician to his obligation under the law. The pre-employment applicant had a child of tender age. The mother felt well, ignored the doctor's diagnosis, sought and obtained employment elsewhere, and within a year was diagnosed as advanced tuberculosis and the sanitarium prognosis is grave. What the plant physician did not realize and probably is not yet aware of is that the result of the report he should have sent would have been medical and nursing follow up and offer of assistance by the Department of Health, persuasive education in the interest of patient and child, a probable early admission to hospital care, avoidance of infection of the child and a rehabilitated life of self-support.

It is well from time to time to remind ourselves that the reassuring progress in control of tuberculosis has been in spite of all the incompletenesses of reporting, in spite of delayed reporting, in spite of the insidious and silent nature of early pulmonary disease and in spite of the entire lack of any specific resources for creating immunity or for cure in the chemotherapeutic sense.

We know so much we do not use that there is no excuse for discouragement or delay. The question is one of relative speeds of progress, always the hope that within our lifetime, our offspring will escape wholly what we know has decimated our predecessors and cruelly handicapped our contemporaries. When my grandparents made their home in New York City in 1838 the death rate in that city from tuberculosis was not less than 300. When my parents started their family in 1868 the rate was 250 or over. In the years when our children were being born in the first decade of this century the rate was about 150. Our grandchildren are living in the same city where a rate of 45 is current today. In each generation but the latest, the disease has exacted its toll of disability or death.

May I suggest that with economy and efficiency we can guarantee freedom of the succeeding generations from tuberculosis if we undertake the following programs—one of discovery

(Continued on Page 41)

THE PROBLEM OF MEDICINE IN RURAL HEALTH

L. W. LARSON, M.D.
Secretary of the North Dakota State Medical Association
Bismarck, North Dakota

I UNDERSTAND that your Program Committee chose me to discuss the problem of medicine in rural health in this symposium because I am a member of the Committee on Rural Medical Service of the American Medical Association. Since I have been a member of this committee only a few weeks and the committee has not issued a report of its findings, the material in this paper is not to be construed as that of the committee.

Rural health has been a problem ever since this country was founded. An increasing interest in rural health has developed, especially during the past fifteen years. The Farm Foundation, Farmers Union, Farm Bureau Federation, Grange, and the Federal Security Administration, have departments or committees devoted to a study of the problem. The Farm Foundation sponsored a conference on medical care and health services for rural people in April, 1944. Representatives of the above-mentioned farm organizations, government agencies, state agricultural colleges, farm publications, medical, dental, and hospital associations, United States Public Heatlh Service, Children's Bureau, United States Senate Committee on Education and Labor, American Legion, National Congress of Parents and Teachers, et cetera, attended the conference. According to the printed report of this conference[1], availability and cost are the two outstanding problems in rural medical care.

We are all aware of the fact that physicians have gradually moved from the strictly rural areas to the larger urban centers during the past twenty-five years. There are statistics available which show that many physicians have moved from the rural states to industrial states. This is especially true in the Southern states and also, to some extent, in the Great Plains states during the drouth years. The war served to increase the shortage in these areas because many physicians chose to enter military service rather than stay in the states with low per-capital incomes. The reasons for this migration are obvious. Inadequate remuneration, the necessity for traveling long distances to reach the patient, lack of hospital and adequate diagnostic facilities, absence of consultation service, long hours of work, inadequate facilities for education of their families and for recreation, and difficulty in arranging for vacations or postgraduate study, have driven too high a percentage of rural physicians into the larger centers. The solution of this problem is extremely difficult. The complaint of non-availability of physicians comes mainly from the sparsely populated areas, particularly the Dakotas, Nebraska, Montana, Wyoming, Nevada, Arizona, New Mexico and Idaho. In these states the population is not only small, but the distance between trading areas and centers are great, roads—except the main highways—are poor, and there are deficiencies in the usual facilities for transportation. It would seem that there is small chance of changing all of these basic factors in this particular area. The problem is to bring the doctor to these people, or to make it possible for the people to get to the doctor.

Much has been written concerning the reasons for the failure of young doctors to locate in rural areas. The most common reason given is that the average small town does not have hospital facilities. A great wave of enthusiasm is spreading throughout the rural sections of this country for the construction of small rural hospitals. However, it will be extremely difficult to bring this about because of the initial cost of construction and equipment, the cost of maintenance, the difficulty in maintaining adequate medical and nursing personnel, and, most important of all, the tendency of rural people to by-pass the local physician and small hospital to consult a physician, and possibly enter a hospital, in the larger center, regardless of the distance. It is true that there are notable exceptions to this rule, for all of us know of practitioners in small towns who have retained the complete confidence of their people and have successfully operated small hospitals in sparsely settled localities. After a rather careful study of the problem in my home states, in which the above-mentioned factors are very apparent, I am convinced that it is unwise for the average small community, even though it be a county seat, to

---

Read at the North Central Conference, Saint Paul, Minnesota, November 11, 1945.

construct a small hospital with about 25 or 30 beds. Several such hospitals were constructed in North Dakota through government grants during the drouth period, but none of them was a success. They failed because it was impossible to hold a successful physician who could do all the things demanded of him, particularly in surgery, even though hospital beds were available. The same fate lies in store for those small communities who attempt to build small hospitals unless the hospital is subsidized in one way or another, facilities for laboratory and x-ray diagnosis are provided, and consultation is readily available. I believe it is much more sensible to encourage the development of small community health and diagnostic centers, strategically located in the smaller towns. Young physicians can undoubtedly be influenced to locate in small towns, provided office facilities, living quarters, and a few hospital beds for obstetrical patients and emergency cases are available. The ambitious young physician, particularly the one who wishes to specialize, will not stay, but his experience will be invaluable, he will probably be able to save a little money, he will be performing a real service to the surrounding rural population, and when he leaves, another young physician can be found to replace him.

The relative cost of a service, or commodity, depends on the income of the consumer and his evaluation of the worth of the service or commodity. The cost of medical care is a problem of great concern to rural people, according to their spokesmen. Of necessity, the cost of rural medical care is relatively high, if the physician is obliged to travel miles to reach the patient. The fees for the actual services rendered by the rural practitioner are not exhorbitant; they are usually much lower than the fees charged for comparable services in urban areas. Improvements in transportation, particularly in the development of good highways which are passable throughout the year, will accelerate the growing tendency of rural people to bring the patient to the doctor. This will reduce the cost of medical care; it will conserve the time of the physician, who, too often, spends the majority of his working hours in traveling to and from his patient.

The most serious difficulty facing the farmer, however, is the variability of his income. This is particularly true in those areas in which there is a sparse population, and in which the factors which tend to increase the cost of medical care because of the distances to the physician and hospital, are present. I believe most students of rural economics will agree that if the income level of farm families could be elevated, at least to the point where it has been during the past five years, there would be very little concern over the cost of rural medical care. Miss Elin Anderson, in summarizing the Farm Foundation Conference held in the spring of 1944, said: "The crux of the problem, as we know, is economic."[2] Dr. R. C. Williams, of the United States Public Health Service, who was chief medical officer of the Farm Security Administration during the drouth years, said, at the same conference: "Perhaps all I have done has been to rear the ugly heads of some impossible questions, but I do think the whole thing comes right back to that; all our discussion, must, although it may wander and veer around, come automatically back to that crux of the situation—in short, to money."[3]

The only solution of the problem of cost of rural medical care is to raise the level of the farmer's income, or, reduce the cost of the physician's services, or, spread the cost of medical care through a prepayment medical insurance plan. The farmer must raise his own income, with the help of Government subsidy, if necessary. A reduction in the rural practitioner's fees cannot be made unless the majority of his patients are brought to him. If his income drops he will simply move on. Prepaid medical insurance will solve the problem, provided it can be operated on a sound actuarial basis, and the farmer is able and willing to pay for it. Many spokesmen for the farmer insist that he cannot afford to spend $48.00 or $50.00 per year for catastrophic medical and hospital protection. The reason given is that his total cash income will not warrant such an expenditure. A government agency has estimated that in 1944, 40 per cent of the farmers had an annual income of $700.00 or less. This is an impressive figure, but does it mean that 40 per cent of the farmers had a *cash net income* of less than $700.00 after the cost of rent and food had been deducted? There are millions of families in urban districts who have a net income of less than $700.00 after the cost of rent and food has been deducted. In considering such figures, it should be emphasized that the remaining 60 per cent of the farm population supposedly had a cash net income of over $700.00 per year. Economists, particularly those who are directing their attention to the cost of rural medical care, might well ask the farmer what he spends his cash income for. Is it not possible that many of them squander $48.00 or $50.00 per year on trivialities, which could well be used for their health protection. This, of course, involves the question of evaluating the things in life. No nation in the world spends as much money for tobacco, cosmetics, candy, movies, etc., as we do in the United States, and this tendency is as prevalent in rural areas as it is in urban areas. Health education will impress all of our people with the value of good health, and the need for budgeting the family income to pay for the illness that will certainly come, whether that payment be on a fee-for-service basis, or it be covered by an insurance plan.

The following four-point program is offered for the solution of the rural medical and health problem:

1. The number one objective in the constructive 14-point program of the American Medical Association for the extension of improved health and medical care to all people is as follows: "Sustained production leading to better living conditions, with improved housing, nutrition, and sanitation, which are fundamental to good health; we support progressive action toward achieving these objectives." A sound agriculture in which the uncertainties of annual income will be reduced to a minimum through irrigation, where necessary, utilization of modern methods and machinery, and the education of the future farmer in our high schools and agricultural colleges will reduce the number of farmers who find it difficult to pay for medical care or health protection.

2. The development of prepaid medical insurance plans which will succeed in the rural areas. Unfortunately, there is not sufficient actuarial data available at present on which such plans can be developed. As physicians, we must assume the responsibility for the development of plans which have some hope for success. In doing so, we should realize that there may be losses, especially at first, but those of us who render the services must be willing and able to absorb the losses. Almost all physicians, and most of the farm organizations in this country, are opposed to a system of federally controlled, compulsory, medical insurance. It would seem wise to explore the possibility of government subsidy of local prepaid medical insurance and hospital plans in those states where definite need is demonstrated, provided, however, that the plans are administered by the proper local agency in the states involved, with the help and advice of the medical profession. This suggestion may be violently opposed by some, but we must remember that the majority of the complaints being offered that medical care is inadequate and costs too much, come from those areas which, because of local economic conditions, may not be entirely able to correct the situation themselves. Federal aid to such areas, under a system in which the funds are controlled locally, will not jeopardize the American system of free enterprise.

3. Expansion of public health facilities. We all know that public health facilities have not been extended to the rural communities as rapidly as they should have been. The reasons are the same as for the fundamental problems discussed above. Trained public health personnel has not been available and rural people have been unwilling to levy sufficient taxes to carry on a successful public health program. In late years, funds have become available through social security funds for the development of more and more public health units. The state health department controls the funds allocated to the unit, usually chooses the personnel, and determines the policies. I believe that we, as a profession, should support a program in which a well-organized public health unit will be developed in every rural community which has a population large enough to support it. Preventive medicine is extremely important, and has not been given its proper emphasis in rural areas. The development of rural public health units will offer an inducement for young physicians to locate in rural areas because they can be placed on a definite income for the public health work they do in the community. In addition, if some of the plans now being made by the Federal Government materialize, office and hospital facilities and living quarters will be provided in the community health center. We must insist, however, if we are to support this program of expanding public health facilities, that preventive and curative medicine be clearly defined. With the control of this program resting in the state or local subdivision, it should be possible to develop a common understanding so that the public health department will not take over the practice of medicine. One of the most important functions of such a health unit will be that of health education, which has been woefully

weak in the past, especially among rural people. When the people know how to prevent disease, and what to do when they are confronted with an illness, they will have a better appreciation of the value of good medical service and will be more willing to pay for it.

4. Continued study of the problem of rural medical care. Each State Medical Association should have a committee to study the problem. The medical profession should co-operate with every agency or organization in the state which is interested in the welfare of the people. We must not only support, but also provide the leadership in, the state health planning committees, whose membership should represent all organizations and interests in the state. Through such contacts we will soon find that the people are keenly interested in the problem of medical care. Laymen may not understand all phases of the problem; they may have some wrong ideas of what can be done, but experience shows that through conferences around the table, a common viewpoint can usually be reached.

WHAT PUBLIC HEALTH EXPECTS OF THE PRIVATE PHYSICIAN

(Continued from Page 37)

of pulmonary tuberculous disease and the other of isolation or adequate sanitary supervision of persons discharging the tubercle bacillus from the nose and mouth. We shall achieve the first objective most quickly and at least cost if we concentrate upon x-ray surveys at public expense of the following five categories of persons:

1. Those with suspicious pulmonary symptoms
2. Contacts with known cases of tuberculosis
3. All general hospital admissions
4. Racial and economic groups showing abnormally high incidence
5. Workers in trades exposed to silica dusts.

To achieve our second goal we must have both popular and unanimous professional support for every detail of diagnosis, reporting and sanitary control of infected persons.

The Sanitary Code of the City of New York like those of most other cities of our country includes ordinances requiring:

1. Reporting of all forms of tuberculosis, by physicians and by persons in charge of hospitals, institutions and dispensaries, giving full name, address and age of the patient, within twenty-four hours of the time when the case is diagnosed. (All such records are to be confidential)
2. Isolation of patients capable of spreading the disease, a duty of the physician, if the patient is in a communicable stage.
3. Exclusion of children with communicable tuberculosis from day-care institutions
4. Exclusion of teachers, custodians, principals, etc., with tuberculosis from public, private or parochial schools
5. Forbidding of spitting in public places
6. Pasteurization of milk
7. Segregation of non-coöperative or recalcitrant spreaders of tubercle bacilli by use of the authority of the courts if necessary.

In closing, let me say that what the public health expects of the private physician is no more and no less than it requires of every other citizen, i.e., prompt compliance with the law. Way over and beyond this, popular opinion and medical tradition look to the medical profession with confidence that each increase in knowledge will be made available, appropriately under the conditions of private practice, and so far as need and economy are dictated by civil government, to give accurate diagnosis, humane treatment to the sick and prevent the spread of communicable disease from the sick to the well.

The medical profession has exercised the disciplines of education and of ethics among its members. Any failures of standards within these fields will be best corrected by giving the facts to the organized local and state medical societies.

King Edward VII of England, when told that tuberculosis is a preventable disease, asked why it has not been prevented. It can be prevented in our time if we use our present resources.

RELOCATION OF PHYSICIANS IN IOWA

JOHN C. PARSONS, M.D.
Secretary, Iowa State Medical Association

Des Moines, Iowa

OUR work on the relocation of physicians in Iowa started about a year ago when the Bureau of Information in Chicago, at the AMA headquarters, sent us a form to be filled in for each county in Iowa. You are all familiar with those forms, I am sure. One side is devoted to information about the health facilities of the county—the hospitals, public health and other medical facilities, number of physicians in each age group. The other side of the form is given over to information about the county itself—its character, location and climate, population, principal cities, schools, retail sales, telephones, miles of highway and dwelling units. The first form also asked for information about the churches in the county.

The American Medical Association provided some of the information from its office, and asked us to obtain the rest. We sent the forms to our county society secretaries and asked them to fill in as much as they could. What they did not provide, we dug up as best we could. Many of them—in fact, most of them—did not list the doctors by age groups, and we had to do this for practically the entire state.

This work was completed in the spring, but we felt it did not give us a complete picture, and so the first of May we wrote every county, stating that a few doctors were asking about locations because of release from service, or because they were physically unfit for service. We asked the counties to let us know if they needed additional doctors, and what towns needed them. We also said, "If you are holding the locations for your own doctors who are in service, and don't want anyone, tell us that also."

We got a pretty good response on that, although the towns which were listed as needing physicians were small ones, 500 to 1,000 population for the most part. Also many counties said they did not want new physicians, but were holding locations for their own doctors in service.

The next step we took may not meet with unqualified approval, but it did give us some clues. We talked to detail men covering the state, asking them where doctors were needed. Usually they could give us the names of a number of towns that really needed doctors.

Next, we began to get requests from doctors who were getting out of service asking about locations. We wrote them very fully of the towns we had listed, giving all of the information we had about them, and giving them the name of the doctor whom they should talk to in each county.

Now many of the doctors are coming into the office to talk over the matter of getting established. Each one is an individual problem, and our method is probably never twice the same in talking to them. We find out whether they have practiced before, whether they wish to start out on their own, whether they want an assistantship to start with, or what specialty they may have. If they have a preference for a certain section of the state, we go over the towns in that locality. We tell them what we know about the county medical society, whether it is active, what the hospital facilities are or what the prospects are for new hospitals. We give them the names of doctors to talk to, and advise them to talk to as many doctors as they can. In fact, we give them as complete a picture as we have.

Some of these doctors have visited various towns in the state, talking to doctors in each place, and they have come back to report that there is a great need for doctors everywhere—that they can settle any place and make a go of it. Persons of their temperament will probably succeed anywhere, too.

Some of them are uncertain, however, particularly when starting out on their own for the first time, and they need encouragement. They are afraid it's going to be a lot tougher than it really will be. These are the ones who are encouraged to locate where there is a stated need for a doctor and where the county medical society will co-operate from the start.

Iowa has many religious communities, and it

LUMBAR SYMPATHETIC BLOCK AND THAT POSTPHLEBITIC LEG

H. O. McPHEETERS, M.D. and H. A. ALEXANDER, M.D.
Minneapolis, Minnesota

THE word "phlebitis" means an inflammation of the vein. This should always be regarded as of serious import. Even though the great majority of attacks of it are of little consequence and clear up spontaneously, we never know just what will happen in an individual case. Phlebitis is one of the most common complications of all types of surgery. It has perhaps most often been seen in the postpartum case, although the surgeon must expect and fear its onset in every case. Most often it involves the deep veins in the lower leg and it is this particular involvement that I wish to discuss here.

The usual history of the onset of a phlebitis is one of surprise. A patient who has made a perfectly normal postpartum or postoperative progress may begin to run a fever of 99 to 100 degrees with no symptoms indicating the cause. Another patient may have a slight pain and tenderness through the calf noticed during the bath, while another patient may have a violent onset with a chill, fever and severe pain through the entire lower leg, followed by extreme swelling of the part even to the crest of the ilium. It is oftentimes difficult to recognize and may only be surmised from the unexplained fever. The Homans signs, with pain in the calf when the muscles are put on tension and tenderness on deep pressure through the calf, are usually positive. The violent case with a typical onset and the secondary findings cannot be missed.

Pathology.—The primary pathology here is one of damage of some type to the intima of the vein wall. This may be due to trauma, infection, or chemicals. This in the presence of a slowed blood stream as we have when a patient is quiet in bed after delivery or after an operation, or with an altered state of the blood constituents, is all that is needed to start the deposit of the blood platelets and the formation of a thrombus. If the process is mild and the injury is very slight, we may have the condition commonly spoken of a phlebothrombosis. In this case the vein is simply filled with a thrombus which is but little more than a simple red thrombus or blood clot similar to the postmortem clot. It is not fixed to the wall of the vein firmly, but on the contrary lies there filling the vein and ready to float onward and upward with the blood stream with the first sudden stimulation of the venous current, as with massage or with active muscular action. This is the thrombus to be most feared. It often produces no symptoms and is the most common source of an embolus. But it is not with this silent phlebothrombosis that we are most concerned in this presentation. It is rather with the severe deep thrombophlebitis with the thrombus firmly fixed to the wall of the vein and which causes the train of symptoms and complications that may last for life that we are particularly interested in at this time.

By their experimental work, Ochsner and DeBakey have shown that the onset of a severe thrombophlebitis causes an overstimulation of the sympathetic ganglia along the lumbar spine with a secondary and resultant spasmodic contraction of the arterioles throughout the extremity. This in turn causes a stasis of the circulation, stagnation of the lymphatic circulation and venous congestion. The leg becomes swollen, mottled and at times almost white. At other times it is cyanotic. This depends on the difference in the degree of the lymphatic or venous stasis predominating. The condition is usually painful and the entire leg is sore and tender. At times the patient complains of even slight jarring of the extremity.

Prognosis.—If no active treatment is given the course of events usually becomes no less than tragic. Too often the doctor has merely commented, "This is just too bad, but we will have to make the best of it." He would tell the patient, "You have a serious complication and will have to rest in bed until nature has repaired the damage." This would often mean weeks and months of bed rest and invalidism, with the ever-present chronically swollen extremity and the cold, clammy, cyanotic lower leg and foot. The later complications of pruritis, eczemas, varicose veins, ulcerations, dermatitis and fungus infections about the lower leg and foot effectively cripple the patient both mentally and physically, and it is these conditions that I wish to discuss.

Presented before the Minneapolis Surgical Society, October 4, 1945.

All the above complications develop on a "stasis basis." Therefore, it is logical that we should approach their treatment in just the reverse order. Rather than treat the skin condition present first, let us attempt to correct the circulation and get more fresh arterial blood to the part with food for the tissues, and get rid of the edema, congestion and stasis with their associated accumulation of plasma proteins and products of tissue damage. It is these that cause the permanent fibrosis in the fascia, which when well developed remains there for life.

If Ochsner and DeBakey were right in their conclusion as to the overstimulation of the sympathetic ganglia as the cause of arteriole spasm, then they were right also with their theory of correcting the spasm by the injection of novocaine to put them out of function. This they did with their "lumbar sympathetic block." They found that by injecting 10 c.c. of one per cent novocaine solution along the area of each of the upper lumbar ganglia, the spasm of the arterioles was relieved and the arteries would again open widely and even more than the normal amount of fresh blood would flow to the part. This would wash on through the tissues and tend to clear them of the stagnation products. In this way, the circulation would gradually return to normal with a healing of the eczemas, ulcerations and fungus infections that had resisted all previous efforts. In many cases the normal state of vitality can never be regained and the complications will tend to recur, but it is the healing of the condition present that we are hoping for and we can then try to prevent a future recurrence. All the usual, accepted treatments for these complications should be used at the same time. The lumbar sympathetic block is merely an additional trump card in our pack of tricks to cure some of the most distressing and annoying end results of an old thrombophlebitis of years before. If the block is used at the onset of the phlebitis, all this chain of events can be prevented and the patient's leg returned to normal, in the great majority of cases in the course of a few days' time.

Case 1.—Mrs. H. B., housewife, thirty-six years old, was seen in May, 1936, with a history of having had a "broken vein" after confinement fifteen years previously, when she had been in bed for several weeks. Both lower legs have swelled much ever since. Examination showed the patient with both lower legs badly swollen, edema grade two, the right worse than the left, and a few scattered veins, size two, over the lower leg. The patient was seen again in May, 1936, with an acute eczema over the right lower leg and foot. Much edema was still present. In June, 1940, the patient was again seen, with extensive eczema about the lower leg and foot, with a severe fungus infection and typical fungus odor. Edema was present in spite of a supportive bandage. The patient was sent to the hospital in August, 1942, for the same condition. In December, 1943, the patient had a repetition of the skin condition with poor response to treatment. At this time I did a lumbar sympathetic block with a very fine immediate response and rapid healing of the skin and dermatitis. When seen in June, 1945, the patient had been well, had used a supportive bandage during the past year, but now has edema grade two without the bandage. The dermatitis had remained controlled.

Case 2.—J. P., a laborer, aged thirty-four, was seen in May, 1942, with a history of a bad thrombophlebitis in the left leg, following a pneumonia in 1933. He had been in bed for three months. The lower leg had been swelled ever since. Ulcers had first appeared in 1937. An open ulcer was now present over the external surface of the lower third of the leg which had been open for the past seven months. There was an extensive eczema and dermatitis over the left lower leg. The patient received some help from a varicose vein ligation and supportive bandage. In 1943 the condition was worse than ever. The feet were cold and clammy and there was a typical severe fungus infection about the ankle and foot. He received much help from a lumbar block, and the skin cleared up more rapidly than before. In April, 1943, Dr. S. Maxeiner and I did a lumbar sympathectomy, removing the upper four lumbar sympathetic ganglia on the left side. There was a marked improvement in the condition immediately. The skin became dry and warm, the eczema cleared entirely, and the edema practically disappeared. In September, 1945, the patient had two slight recurrences of the ulceration on the lower leg following trauma but each of these healed well with support. The patient now has little or no edema when wearing the supportive bandage.

Case 3.—J. E. S., a grocer, aged forty-five, was seen in July, 1944, with the history of having had varicose veins since the first world war. He had had ulcers on the inner and external surfaces of both ankles for the past six years. When seen at that time he had an ulcerating eczema with a fungus infection about both ankles and feet giving a typical fungus odor. The feet were cold and clammy and there were extensive varicose veins of both legs, involving both the short saphenous groups and the left great saphenous group. There was edema, grade two, of both lower legs and feet. I did a ligation of the left great saphenous and both short saphenous veins, with much relief. The patient continued to have recurrent attacks of the dermatitis about both the ankles, not severe, however. When seen in April, 1945, the edema was still grade one, with dermatitis and superficial ulcerations about both ankles, even if the patient wore a tight supportive bandage. I did a lumbar sympathetic block on the left side and later on the right side. This was repeated ten days later. When seen in September, 1945, the edema was almost gone and the patient wore bandages only half of the day. The skin condition was entirely healed and the skin was dry and warm. I advised him that if he should have any recurrence, he should have a lumbar sympathectomy.

Case 4.—A. P., a mechanic, fifty-seven years old, was seen in December, 1942. He gave a history of trouble in the right leg for thirty-three years, beginning with a bruise, and followed by milk leg which had been present ever since. The patient had had recurrent attacks for the past fifteen years and the leg had been swollen continuously for the past five years and is now very painful. Examination showed the right lower thigh about four inches larger than the left and the right lower leg at the mid-third three and one half inches larger than the left. There was a very extensive necrotic ulceration over almost all of the lower half of the left lower leg anteriorly and a weeping eczema about the ankle which was very painful. The great saphenous vein was size three in the groin and size two in the thigh and there was much cellulitis of the tissues of the lower leg. The patient was put in the hospital and hot packs were applied. Later 200 Braun seed grafts were implanted into the ulcer area and later a saphenofemoral ligation was done. In February, 1944, I did a lumbar sympathetic block. Today the patient has but little edema which is well controlled with the bandage. The ulcers are healed, and the skin is dry and warm. The patient will always have to wear some type of support part of the time.

In conclusion, I would emphasize that the lumbar sympathetic block is of much more value and importance in the treatment of thrombo-phlebitis than has been commonly recognized by the profession. The results following its use in the acute case are often miraculous. We now find that the chronic case with semi-invalidism of years' duration due to the edema of the lower leg with the complicating dermatitis, stasis eczemas, and ulcerations can be helped a great deal by its use. It should be employed in every such case.

RELOCATION OF PHYSICIANS IN IOWA

(Continued from Page 42)

is wise to bear that fact in mind when advising a young doctor. If he is a Lutheran, he may be happier in a location in which the majority of the people are Lutherans. We had an instance this week in which a young man was definitely attracted to a certain opening, but it was a Catholic community and he was not a Catholic. He finally decided against it, and this was probably a wise decision.

In the final analysis, the doctor himself is the only one who can decide where he will locate. Probably the best service we can offer is talking to him. When we sit down and tell him all we know about each opening, bringing out the special features of each one, its background, the little personal things we may know about, then we have given him a yardstick by which he may measure it. We also feel it is important to direct him to a physician we think will take time to talk to him and go over the situation with him."

After we give him all of this information and background, he may go out, look over the place, and not like it at all. He may find an opening we didn't know existed, and we feel pretty futile. We really feel we have little concrete to offer. We have a list of about twenty towns, all but three or four under 1,000 in population.

The best we can do is give each man our personal attention, encourage him, and give him as complete a picture as we can. Possibly the many little things we mention help him set up certain criteria in his own mind which he may utilize in coming to a decision. Some of the younger men have no yardstick by which to measure a location, and maybe we help them attain it.

We're glad they are demobilized, and we hope they find a good location in Iowa. If we can get across to them the fact that they are wanted and that there is a place for them, maybe we are of some help.

MEDICAL EXPERIENCES AT DACHAU

MAJOR JACK A. KILLINS, MC, AUS
and
CAPTAIN JOSEPH L. POSCH, MC, AUS

THE German concentration camp operated by the SS troops at Dachau has received widespread publicity. Because of this general interest we have considered it worth while to record our medical observations made between May 3 and June 12, 1945, while we worked at Dachau with the 127th Evacuation Hospital. We have adhered closely to an objective recording of our own experience. The horrors of the camp with their social and political implications have been left to other better qualified writers. In limiting our discussion to the cases we have personally examined and cared for, we have made certain deficiencies inevitable. We were originally assigned as a surgical team. However, the influx of patients and the preponderance of medical cases soon required that we assume care of approximately half the patients with pulmonary tuberculosis as they were diagnosed and segregated. All known cases of typhus in males were sent to the 116th Evacuation Hospital where the care of selected cases was supervised by members of the U. S. Typhus Commission. Consequently, the amount of tuberculosis reported by us is disproportionately high, while the amount of typhus in the camp is in no way indicated by the few cases we saw and diagnosed after they had been admitted to our wards. Our surgical cases are fairly representative of the entire camp.

We examined and cared for 308 patients of the 2,268 admitted to the 127th Evacuation Hospital during its stay in Dachau. All patients were white; there were 10 females and 298 males. The nationalities represented and the number from each nation are indicated in the following list:

Polish	93	Rumanian	8
Russian	57	Dutch	6
Hungarian	30	Lithuanian	5
Italian	24	Austrian	3
Yugoslav	20	Spanish	2
Czechoslovakian	18	Greek	2
French	15	Estonian	1
German	11	Latvian	1
Belgian	8	Nationality unknown	2

The average age was 31.7 years. Our youngest patient was thirteen and the oldest was sixty-seven. Forty-seven of our patients were twenty or less, twenty-four were fifty or more.

In almost every case the patients were extremely thin and weak. They were tired, listless and disinterested in either their surroundings or in their recent liberation. As they were admitted, patients were bathed in soap and water and 2 per cent cresol solution, their scalps shaved, their bodies dusted with DDT powder, and they were taken through the x-ray department for radiographs of their chest. Many arrived on the wards completely exhausted. Their average weight on admission was 117 pounds; the lowest weight recorded for an adult was 86 pounds. A very few who had been imprisoned but a short time or who, because of their technical skills, had received extra rations, had weights approximating normal.

Ninety-nine patients suffered from one or more infections in the skin or subcutaneous tissues. These included acute abscesses, old incised or spontaneously draining infections which left indolent ulcers of months' duration, and deep-seated, poorly defined areas of inflammation in the subcutaneous tissues. Decubitus ulcers were common. The combination of extreme emaciation, weakness and unpadded wooden slabs for beds was so conducive to their development that it is only remarkable that there were not more such cases.

Twenty-seven wounds of external violence, including three compound and two simple fractures, occurred during the two weeks preceding our arrival at the camp. These patients were cared for initially at the prison camp hospital whose facilities were hopelessly inadequate. All the wounds were frankly suppurative when we saw them. Older wounds and injuries accounted for seven other cases. There were seven patients with osteomyelitis originally caused by some injury inflicted by the German SS troops or by an injury accidentally incurred in the prison compound.

Ten men had gangrene. In at least three cases the history clearly indicated the gangrene was a

---

Major Killins has been relieved from active duty and has resumed his fellowship in surgery at the Mayo clinic, Rochester, Minnesota. Captain Posch formerly lived in Saint Paul, Minnesota.

complication of typhus fever. Two of these men had bilateral symmetrical gangrene of the feet. The third had a sharply defined gangrenous area in the left cheek extending completely through the buccal tissues into the mouth.

There were five amputations of the lower extremities which had been performed in the prison hospital. All were of the guillotine type. These patients were in relatively good general condition and their amputation stumps covered with granulations.

Nineteen patients suffered from scabies. Many of the scabetic burrows were secondarily infected. In all cases the scabetic infection was incidental to some other condition requiring hospitalization.

Eleven high fevers with headache and mental confusion among our patients were diagnosed as epidemic louse-borne typhus and transferred to the hospital designated for such cases. The diagnosis was subsequently confirmed by the appearance of a typical rash and the appearance of proteus agglutinins in the circulating blood.

Enteritis with diarrhea appeared in forty cases. The patients themselves ascribed this to the increased food intake since their liberation. The recent onset and the infrequency of pathogens in the stool cultures tends to confirm the observation of the patients. In one case, Shigella paradysenterii Type IV was cultured from the stool, and in another, Shigella ambigua was found. Following a paroxysm of coughing, one patient found an adult Ascaris lumbricoides in his sputum cup.

There were two cases of parotitis, both of which responded to penicillin and hot packs. Neither required surgical drainage.

Seven cases of bronchial pneumonia developed while under our care. None of these patients died.

We saw 115 patients in which the roentgenologist had made an unequivocal diagnosis of pulmonary tuberculosis. Seven more were observed in which the roentgenologist reported bronchopneumonic infiltration, suggestive but not typical of tuberculosis.

Acid-fast bacilli morphologically typical of mycobacterium tuberculosis were found in the sputum of thirty-nine patients. Since the laboratory facilities were strained, not all patients had sputum examinations and it was impossible to repeat the examination more than three times on any patient.

Forty-two patients with pulmonary tuberculosis had some additional unrelated condition such as a cutaneous ulcer, gangrene of an extremity or a wound of external violence.

Four tuberculous patients had draining sinuses in an extremity with marked lime salt absorption of the osseous structure distal to the sinus and a presumptive x-ray diagnosis of tuberculous osteomyelitis.

One of these patients, a nineteen-year-old Belgian with bilateral pulmonary tuberculosis and an x-ray diagnosis of tuberculous osteomyelitis of the left metatarsals, became irritable, apprehensive, frightened and hypertonic. His neck became rigid and bilateral ankle clonus was present. Spinal fluid examination revealed chlorides 595.7 mg. per cent, protein 135 mg. per cent, 95 white blood cells per cu. mm. (100 per cent lymphocytes), sugar 54.1 mg. per cent, colloidal gold 5555555531, Wassermann negative. Culture for routine organisms was negative. Examination of the centrifuged sediment was negative for acid-fast bacilli. A guinea pig was inoculated with the spinal fluid after three days of treatment but this report is not available. Treatment with fourteen daily intrathecal injections of 20,000 Oxford units of penicillin in 10 c.c. of physiological saline plus 20,000 Oxford units of penicillin intramuscularly every three hours was followed by a remission of all central nervous system symptoms and a return of the spinal fluid to normal.

The average hemoglobin recorded was 66 per cent (Tahlquist), a higher figure than we anticipated, considering the general debility of our patients.

The white blood counts recorded were not remarkable. The proportion of patients with more than 10,000 leukocytes per cu. mm. correspond closely to the proportion of patients with abscesses or other pyogenic infections. Only seven had leukocyte counts of less than 5,000 per cu. mm.

Cultures of the exudate from infected wounds and the material from abscesses revealed the following pathogenic organisms:

Streptococcus pyogenes hemolytic	18
Proteus species	10
Staphylococcus albus nonhemolytic	7
Diptheroids	5
Staphylococcus aureus hemolytic	4
Escherichia coli	3
Salmonella enteritidis	2
Staphylococcus aureus nonhemolytic	1
Aerobacter aerogenes	1
Corynebacterium	1

RECORD OF PATIENTS WHO DIED

Case No.	Age	Nationality	Time in Hospital	Remarks	Autopsy	Laboratory Findings
1	45	Hungarian	12 days	Abscess over rt. scapula I & D 1,000 c.c. pus, severe intractable diarrhea. Died 10 p.o. day. Generalized anasarca, acute embolic and glomerular nephritis. Cirrhosis of liver. Extensive ulceration transverse colon. Pulmonary tuberculosis.	Yes	Hb 56%, WBC 4,100, RBC 2,920,000, Plasma proteins 4.9, Hematocrit 28.5. Urine: alb two plus, pus cells 2 HPF, RBC 25 HPF, granular casts. Wound culture: Salmonella enteritidis. Stool culture: Negative.
2	40	French	12 days	Severe subcutaneous infection lt. lower leg incised prior to admission with necrosis of skin around incisions. Rt. empyema treated by multiple aspirations. Extensive bilateral caseous tuberculosis with cavitation, severe malnutrition.	Yes	Hb 65%, WBC 27,700. Plasma proteins 4.5. Hematocrit 27; Urine neg. Leg wound culture: Proteus spp., Strep nonhemolytic.
3	22	Russian	12 days	Gun shot wound left hand and left thigh. Three massive hemorrhages from lower bowel. Numerous sharply marginated ulcers in colon.	Yes	Hb 68%, WBC 7,150, RBC 3,420,000. Plasma proteins 4.8. Hematocrit 29.2. Bleeding time 2.5 min.; clotting time 4.5 min. Hand wound culture: E coli. Staph albus hemolytic. Strep. viridans.
4	50	Hungarian	18 days	Gun shot wound rt. knee compound comminuted fracture prox. end rt. tibia. Suppuration rt. knee joint and subcutaneous tissues of entire post aspect of rt. leg.	Yes	Hb 55%, WBC 5,800. Wound culture: proteus spp.
5	20	Yugoslav	19 days	Bilateral severe pulmonary tuberculosis. Left tuberculous empyema. Tuberculosis of liver and spleen. Severe malnutrition.	Yes	Urine neg. Sputum: numerous acid fast bacilli.
6	36	Polish	22 days	Pulmonary tuberculosis with cavitation, all lobes. Tuberculosis of liver and adrenals. Severe malnutrition.	Yes	Hb 55%, WBC 6.650. Urine alb. 2 plus. Sputum: pos. for acid fast bacilli.
7	45	Polish	22 days	Pulmonary tuberculosis with cavitation, all lobes. Tbc of liver, spleen and kidney. Severe malnutrition.	Yes	Hb 65%. WBC 3,200, RBC 4,390,000. Urine neg.
8	49	Polish	3 days	Severe malnutrition with edema and heart failure.	Yes	None.
9	41	Polish	6 hours	Left and right heart failure, edema, anasarca, exhaustion.	Yes	None.
10	29	Russian	2 days	Severe malnutrition. Left empyema.	No	None.
11	25	Belgian	2 days	Sucking gun shot wound left upper chest 3 weeks old. Malnutrition, exhaustion.	No	None.
12	42	Czech	3 days	Dry gangrene, left lower leg and inner thigh. Malnutrition.	No	None.
13	51	Polish	3 days	Large dirty ulcer in rt. floor of mouth. Decubitus ulcer over left trochanter, intractable diarrhea.	No	None.
14	21	Russian	23 days	Bilateral pulmonary tuberculosis. Malnutrition.	No	Hb 60%. WBC 10,800.
15	21	Russian	16 days	Rt. pulmonary tuberculosis. Extreme emaciation.	No	Sputum: pos. for acid fast bacilli. Hb 60%, WBC 3,200.
16	26	French	1 day	Bilateral pulmonary tuberculosis; bilateral tuberculous epididymitis. Extreme emaciation.	No	None.
17	53	Yugoslav	7 days	Bilateral pulmonary tuberculosis with pleural effusion.	No	Urine negative.
18	21	Russian	3 days	Severe emaciation. Exhaustion. Chest X-ray: Bronchopneumonic infiltration left base.	No	None.
19	38	Polish	18 hours	Enteritis 4 months. Severe terminal diarrhea.	No	None.
20	31	Hungarian	6 days	Intractable diarrhea. Severe emaciation and exhaustion.	No	None.
21	23	Czech	20 days	Rt. pulmonary tuberculosis. Large ulecration over rt. scapula. Extreme emaciation and weakness.	No	Hb 50%, WBC 13,000. Urine neg. Sputum pos. for acid fast bacilli. Hematocrit 27. Plasma proteins 8.2.
22	27	Russian	28 days	Bilateral pulmonary tuberculosis. Congestive heart failure.	No	Not available.
23	20	Russian	31 days	Infected gun shot wound lt. thigh. Left pulmonary tuberculosis. Severe malnutrition.	No	Hb 60%, WBC 6,900. Sputum pos. for acid fast bacilli.

Mixed infections were common. The two cases of Salmonella enteritidis abscess are of particular interest.

Treatment was directed toward an improvement in the patients' general condition by good nursing care and adequate diet with vitamin supplements. Plasma and whole blood were available and were extremely valuable in the initial phases of treatment. Penicillin was valuable in many of the infected wounds and subcutaneous infections. It was not a substitute for adequate surgical drainage.

Except for a few small plastic procedures performed late in our stay at Dachau, surgical activity was limited to the incision and drainage of infected wounds and abscesses and the application of appropriate plaster splints and casts.

The accompanying table presents the pertinent facts concerning the twenty-three patients who died after admission to our wards.

Comment

Newspaper accounts of sick, displaced persons imply that they can be dealt with en masse. This concept is erroneous. Proper medical care always resolves itself into the examination, diagnosis and care of the individual patient.

In time of war, with atrocities and acute epidemic diseases rampant, the importance of tuberculosis is sometimes overlooked. Its ravages will be felt long after more dramatic events and epidemics have been forgotten.

Summary

We have presented a résumé of our medical observations at the Dachau Concentration Camp. The simple recording of these facts does not portray the sufferings of the patients, nor the unbelievable horrors of the camp. The human values are apparent, however, even in this factual report.

NEBRASKA REPRESENTATIVE MILLER PRAISES WORK OF MEDICAL SERVICES

The following statement, given by the Honorable A. L. Miller of Nebraska in the House of Representatives, is reprinted from the November 23, 1945, Congressional Record:

"Mr. Speaker, the record of the medical men and the medical service in this war is outstanding. It has never been equalled by any Army in any war. There were over 570,000 wounded in World War II, of whom 360,000 were returned to some type of duty. There were some 25,000 or approximately 4 per cent who died of wounds.

"In World War II, only six men in each 10,000 died of disease each year. This is a lower death rate in disease than that of civilians in the same age group here in the United States; yet these men lived in every part of the world under adverse physical and sanitary conditions. In World War I, 165 in each 10,000 died each year of disease, and these men were serving only in the United States and in Europe; the death rate in the Union Army in the Civil War was 712 per 10,000.

"The death rate from pneumonia has been reduced from 24 per cent in World War I to six-tenths per cent in this war. The death rate for meningitis has been reduced to 4 per cent in this war as compared to 34 per cent in World War I.

"I am sure, Mr. Speaker, that the Congress and the country can look with considerable pride upon this fine record of the medical service. There is no record in civil life or elsewhere to compare with this, and certainly a good job has been done in preventive medicine, as well as in the treatment of disease."—*News Notes*, No. 34, Office of Surgeon General.

ARMY DISCHARGES

According to the office of the Surgeon General more than 15,000 physicians have been released from the Army since V-E Day. An additional 15,000 have been made eligible for discharge, which will make a total of two-thirds of the physicians in the Army on V-E Day. Over 3,500 dentists have likewise been discharged from the Army since V-E Day and another 5,000 have been declared eligible for discharge. This will constitute 55 per cent of the 15,000 dentists in the Army on V-E Day.

New requirements provide for discharge of physicians and dentists over the age of forty-eight or after the completion of forty-two months of service, except for certain specialists whose services are required for the care of sick and wounded in Army General Hospitals.

Some 22,000 Army nurses have been discharged to date of the 57,000 which represented the peak strength of the corps. Twenty-seven thousand had formerly been qualified to return to civilian life and new regulations add an additional estimated 12,500.

NOTES ON THE HISTORY OF MEDICINE IN HOUSTON COUNTY PRIOR TO 1900

By NORA H. GUTHREY†
Mayo Clinic
Rochester, Minnesota

(Continued from the December issue)

George Nye was born at La Porte, Indiana, on March 12, 1845. The medical school from which he was graduated is not known, but it is recorded that beginning in 1868 he practiced medicine for many years and that he was a member of the National Eclectic Association. The first scene of his work as a physician was Papillion, Sarpy County, Nebraska, and it was there he met Rose L. Maryatt, a graduate of Milton College, Wisconsin, to whom he was married soon afterward.

In 1874 Dr. and Mrs. Nye moved from Nebraska to New Albin, Iowa; from there in 1877 to Riceford, Spring Grove Township, Houston County, Minnesota; and in 1879 to the flourishing village of Caledonia a few miles northeast. Of their four children only two, Jennie May, aged six years, and Charles Jesse, aged two years, were living in the early eighties when the family was still in Caledonia.

As has been stated, there were other physicians in the village at the time of Dr. Nye's residence, notably, Drs. McKenna, O'Connor, Dustin, G. L. Gates, probably Castle and Freeman, and others in overlapping periods of practice, the exact years of whose presence in the community have not been determined. It is remembered by senior residents that Dr. Nye had his office at the corner of Decorah and Main Streets.

By 1883 a Dr. George Nye, who held Minnesota state exemption certificate No. 420-3, was practicing medicine in Hubbard County. He died in Park Rapids on May 10, 1918.

John S. O'Connor was born on March 2, 1816, in the County of Cork, Ireland, as were the other members of the immediate family. Of his several brothers and sisters, one brother, William, also came to the United States.

After John S. O'Connor had received his early education in the schools of Ireland, he studied at the University of Edinburgh, Scotland, and was a university student in England. On coming to America he entered Rush Medical College, in Chicago, from which he was graduated with his degree of Doctor of Medicine in 1858. Immediately afterward he began a medical practice in Illinois that was interrupted about three years later, at the outbreak of the Civil War, when he entered into military service. For the next three years he was Surgeon, United States Army, First Section, Third Division, Cumberland United States Hospital, at Nashville, Tennessee, and he was with his regiment on the battlefield as well.

In 1866, well prepared by formal training and by both civilian practice and military medical and surgical experience to meet the exigencies of a heavy general practice in a pioneer region, Dr. O'Connor, a man of enterprise and energy, settled in Caledonia, to follow his profession and to open one of the first drug stores in Houston County. Like many another early physician, he had been educated in both pharmacy and medicine. The second drug store in the village was operated by C. P. Coe. It has been recalled of this period in Caledonia that on September 9, 1867, the village post office was empowered to issue money orders and that, a matter of record, Dr. O'Connor was the first person in the settlement, two months later, on November 9, to avail himself of that service. Caledonia, in the later sixties, had about 700 residents. There were many Germans, Norwegians, Irish, and other settlers, of English and Scotch descent, that had come in considerable numbers from New York and the New England States. With his fellow residents, among them a varying group of physicians, some of whom have been named in preceding sketches, Dr. O'Connor was influential in building up a thriving village in a rich farming community and with them he prospered, owning, in addition to his drug store, other property in the little town and also a number of farms near by. The coming of the narrow gauge railroad, in 1879, discussed earlier in this paper, brought the community new growth and stability.

John S. O'Connor was twice married. Of his first marriage, to Ann Starkey, a Canadian, there was one child, John O'Connor. After his wife's death, Dr. O'Connor was married on April 16, 1860, at Cresco, Iowa, to Julia Ann Farrell, who was born in Ireland on August 14, 1843. A trained nurse by profession, Mrs. O'Connor ably assisted her husband in caring for his patients. Of the second marriage there were ten children, most of whom lived into mature years: Mary O'Connor Everett, a teacher; Thomas, a teacher and owner of a newspaper; Jennie O'Connor Schellinger; William, an electrical engineer and contractor; Edward, an attorney and newspaper owner; Nellie O'Connor McQueen; Arthur, who was a senior at Rush Medical College at the time of his death in 1901; Christopher; Charles; and Fergus, a graduate of the Chicago Dental College in 1902 with the degree of Doctor of Dental Surgery.

Dr. John S. O'Connor died in Caledonia on October 11, 1880. For a considerable time after his death Mrs. O'Connor maintained the home in Caledonia and owned and managed the drug store. Long afterward, when the two-story building that had housed the store and the home of the family was being razed, a resident of the village who chanced to be walking near the site picked up a slip of paper that came fluttering down the sidewalk in the breeze; on it was printed, "Dr. J. S. O'Connor, Druggist and Surgeon, late of the U. S. Army."

A well-known member of his profession in the community and county, a Mason and a member of the Episcopal Church, Dr. O'Connor still lives in the memories of early residents of Caledonia, recalled for his forceful and interesting personality and for his professional service to the community. In the early years, when at seasons the roads were almost impassable, he traveled long distances on horseback, as did his colleagues, to see his patients in the outlying communities, conveying his drugs and instruments in leather saddlebags. Under more favorable conditions he used horses and buggy and then carried with him extensive professional equipment superior to the average of that day.

Among the pioneer physicians of his period Dr. O'Connor was unusual in that he had and used a gift of writing to record in many essays and articles, unpublished, his observations and experiences in a widespread and varied practice. Of his manuscripts many, in 1943, were in the possession of his son, Dr. Fergus O'Connor, of Chicago, the only member of the family then living.

Christen K. Onsgard, one of the eight children of Mr. and Mrs. Knute Onsgard, both of whom were natives of Hallingdal, Norway, and among the earliest settlers in Spring Grove Township, Houston County, was born at the farm home on April 10, 1863. He acquired his early education in the local public and parochial schools and in 1884 entered the Eclectic Medical Institute at Cincinnati, Ohio, from which he was graduated in 1887, in the same class with his brother, Lewis K. Onsgard. Returning to Minnesota, he was licensed to practice in the state, receiving certificate No. 1460 (E), and opened an office in Spring Grove. After five years, however, he moved to Halstad, Norman County, Minnesota, where he remained until 1899, when he returned to southern Minnesota to establish himself in Rushford, Fillmore County. In Rushford for nearly twenty-one years he was identified with the community as one of its most constructive citizens and an able and progressive physician. In 1920 he moved once more to Halstad, where he spent the remainder of his life, in active practice until failing health forced his retirement in 1929. He died in Halstad on October 21 of that year. A more detailed account of his life is included among notes on the lives of physicians who practiced in Fillmore County before 1900.

Lewis K. Onsgard was born on a farm in Spring Grove Township on January 1, 1866. His father and mother, Knute and Bergit Larson Onsgard, natives of Hallingdal, Norway, had come to Minnesota in the early fifties and were among the first settlers in Houston County. Mr. Onsgard was the finest type of pioneer—thrifty, honorable and hard working, an intelligent and useful citizen, active in community affairs. A loyal churchman, he helped to build the Lutheran Church of the settlement. It was characteristic of him that he wanted to give his children the best that lay within his ability and means. Mrs. Onsgard was an ideal wife, a woman of unusually kindly disposition, ambitious and capable, a good housewife and a devoted mother. One of her special pleasures in later life was to make an exquisitely knitted bedspread for each of her eight children, who were: Lewis K., Christen K., Kari (Mrs. Gullings), Guro (Mrs. Traaen), Bella (Mrs. Evenson), Maria (Mrs. Gunvaldson), Ingeborg (Mrs. Thore E. Jensen) and Martin.

Lewis K. Onsgard received his preliminary education at the public and parochial schools of Spring Grove, working at the same time on the home farm and preparing even then for his future profession. His brother-in-law, Dr. Thore E. Jensen, husband of Ingeborg Onsgard, encouraged him and Christen to study medicine and to enroll at the college from which Dr. Jensen had graduated ten years earlier, and accordingly, in 1884, the brothers entered the Eclectic Medical College of Cincinnati, Ohio, from which, on June 7, 1887, they received together their degrees of Doctor of Medicine. Although Dr. Lewis Onsgard stayed on at the college for three months to take postgraduate work in ophthalmology, otology, rhinology, and laryngology, he at once applied for his license to practice medicine in Minnesota and on

June 22, 1887, received certificate No. 1461 (E), which three days later he filed in Fillmore County, which was to be the scene of his first practice. In addition to being a physician he was, also, like many other medical practitioners of the period, a registered pharmacist.

On his return from Cincinnati Dr. Onsgard settled in Harmony, Fillmore County, as he had planned, a location with which he was satisfied and in which he was successful. That he did not stay there came about through coincidence. On May 20, 1889, he was married to Anna Laugen, of Houston, an American of Norwegian descent, who was born at Broadhead, Wisconsin. Through his wife he became acquainted in Houston and came to know especially well Dr. Henry P. Johnson of that village. When, in 1892, Dr. Johnson decided to follow his profession in the city of La Crosse, Wisconsin, he persuaded Dr. Onsgard to take over his practice in Houston. The move to Houston proved to be an advantageous and happy one and Dr. Onsgard remained in the village forty-six years, until his death. As was common among physicians in those years, he had his office in his home. That he was a successful physician who possessed the confidence and esteem of his patients and of the community is not surprising, for he was trustworthy and conscientious and used good judgment based on sound knowledge. Although naturally serious he had a keen sense of humor, a trait that was appreciated especially by young folk and children, many of whom he helped through the stress of illness or injury by his timely little jokes.

In addition to carrying on a large local practice, Dr. Onsgard served on the staff of the General Hospital of Winona, Minnesota, and often was called in consultation with physicians elsewhere. He was a charter and affiliate member of the Houston-Fillmore Medical Club; a member, and its treasurer, of the Houston-Fillmore County Medical Society; a member of the Minnesota Valley Medical Association, which in 1911 joined with the Southern Minnesota Medical Association; the Minnesota State Medical Association and the American Medical Association. In his township and county he held various offices in which he untiringly gave of his ability for the welfare and improvement of the community. For many years he was a member of the local board of health; was coroner two years, from 1893 to 1895; county physician; and secretary of the local United States pension board. He was interested in fraternal organizations and was a supporting member and regular attendant of the Lutheran Church.

Early in his career Dr. Onsgard was appointed local company surgeon for the Chicago, Milwaukee, St. Paul and Pacific Railroad Company, a capacity in which he served until his death, and he was a member of the Congress of Railroad Surgeons. His service as railroad surgeon was the occasion of an unpleasant incident, unique in his practice, in which, however, he was exonerated completely. A railroad employe whom he had treated for an injury of the neck alleged that the treatment had not been the proper one and brought suit against the road. When he lost the case, he sued Dr. Onsgard for damages. Eventually the case came before the Supreme Court of the state, where it was thrown out. A pleasant occasion was one on which, when he had taken a railroad employe to Rochester for treatment, he was entertained at the home of Dr. Charles H. Mayo; young Charles, so small, that he was in a high chair, was at the family table. The friendly, kindly atmosphere pleased Dr. Onsgard and on his return home he commented, "That is a real American family." It amused him in later years to recall that once when talking with the Mayo brothers he had told them that they would have to build an addition to their hospital. "Oh, no," they said, "we've got more patients now than we can take care of." Years afterward, at a meeting of the "four-county" medical society in Rushford, when the three men were reminded of the conversation, he was delighted when the brothers told him, "We had to build that addition after all."

Dr. Onsgard began his practice before the days of all-weather roads and powerful automobiles and his experiences were those of his fellow physicians throughout the region. In the first part of his medical career he kept five or six good driving horses in order to meet the demands of his practice, and when his own horses were weary from long hard trips he hired a team and driver from the livery stable. When automobiles appeared, he was one of the first to recognize their potential value to physicians and his Ford car was the first motor to be used in Houston, as his Snowmobile, for winter driving, was the first of its kind in the community. Perhaps his greatest general interest outside of his professional and civic work was to observe and to promote as much as possible the development of the highway system; and simultaneously with improvements in roads he followed with keen interest the steady improvement in automobiles. His immediate personal interest was in his farm, which always was managed efficiently. In his later years, one of his chief pleasures was to go for rides, in a comfortable automobile equipped with heater and radio, to the farm, and about the scenic countryside over which he had driven horses under all conditions of weather, in all seasons, day and night, when roads had been uncertain and often dangerous.

His friends and old-time patients tell of many of Dr. Onsgard's hazardous experiences in attempting to reach his patients. Two such occasions are noted here. In March, 1897, at a time when all the streams in the region were in flood, the doctor was called on a confinement case. As it happened, the patient had been moved to the home of friends who lived near the main traveled road so that she might be nearer medical aid, but the bridge on this road suddenly was washed out, leaving the house inaccessible except by boat. With two men at the oars Dr. Onsgard attempted the crossing. In the savage current the boat soon was out of control and rapidly was drifting close to the milldam. One of the oarsmen, in terror, threw off his coat and was about to plunge into the water to try to swim ashore and, with difficulty, was persuaded by Dr. Onsgard, who knew that no swimmer could live in that deadly flood, to take the oars again. After a desperate struggle they reached the bank and the doctor attended his patient. At a later period the occasion again was a confinement case, out on the South Ridge eighteen miles from Houston. It was winter, and when the driver and team called for Dr. Onsgard, a blizzard was raging, obscuring the houses on the opposite side of the street. They set out, nevertheless, and with great difficulty groped their way along the valley by following the fence posts and telephone poles. Finally, on the Ridge, they were about to give up in despair. The team was exhausted even though the two men had taken turns walking, and there was no sign of a road. At the moment when they had reached an abandoned cattle shed, where they would have taken poor refuge, they saw a light in the near distance. It proved to be in the home of a farmer, who hitched up his horses and took them to their destination, where they arrived just in time, for the patient was in convulsions. Always the physician, Dr. Onsgard forgot his fatigue and discomfort. The mother and the baby boy lived, to the lasting gratitude of the family.

Dr. Onsgard died in Houston on October 24, 1938, of arteriosclerosis. He was survived by one brother, Martin; one sister, Mrs. Thore E. (Ingeborg) Jensen, both of Spring Grove; by his wife and all of their five children: Orrin C., a dealer in Ford automobiles at Houston; Agnes, a teacher of piano, who had a studio in the family home at Houston; Laura, Mrs. Axel Hanson, of Albert Lea, a graduate of St. Olaf College and a former teacher in the Albert Lea High School; Ruth, Mrs. P. F. Johnson, of Houston, a graduate of a teachers' college and a former teacher in the Houston schools; and Dr. L. Kenneth Onsgard, of Houston, a graduate of St. Olaf College and of the Medical School of the University of Minnesota. Dr. L. Kenneth Onsgard, who joined Dr. Lewis K. Onsgard in practice in 1929, has his father's surgical instruments and his fine medical library.

It is not strange that Dr. Lewis K. Onsgard was valued, respected and loved by his fellow citizens and that he is held by them in honored memory. The words of one friend, typical of many, express their regard:

> Perhaps no person outside the immediate family of the late Dr. Onsgard knew him as intimately as I. Being that during a period of twenty-three years I was a practicing druggist, and he my outstanding patron, we have much in common.
>
> He had a wonderful personality—kind, agreeable, and considerate—unusually mild in temper, and not once did I see him lose it. I never had a better and truer friend nor could a near and friendly relative have shown more interest in my success than he. He was strictly honest, not now and then, but always. That he was a successful practitioner is common knowledge and upon that I need not dwell. I shall always remember him as one who made my life more easily lived and enjoyed. Long live his memory.

Harry S. Piggins, a graduate, in 1885, of Rush Medical College, was certificated in Houston County in that year, having received Minnesota state license No. 1036 (R) on April 17. Record exists that in 1909 he was practicing medicine in Milwaukee, Wisconsin. It is hoped that more can be learned about him. In Caledonia, where he was in practice for several years, he has been described as a small man, dignified, a competent "doctor."

John Edwin Pope was born at Carroll, New York, on February 16, 1836, and died at Caledonia, Houston County, on January 19, 1909. A nephew of Dr. Timothy Arnold Pope, who was one of the earliest physicians in the county, John E. Pope in the sixties studied medicine under his uncle's preceptorship and thereafter practiced in Caledonia.

On October 23, 1859, John Edwin Pope was married to Betsy M. Woodward. Of the two children of the marriage, Charles Lineas and Eva Luella, the daughter, Mrs. Eva L. Evans, of Minneapolis, survived in 1941. The following excerpt from her letter of October 14, 1941, gives the clearest available picture of Dr. Pope:

> . . . I remember so little of my father as a physician. I was a little girl at that time. I can just remember a few instances of his going to or coming from calls, . . . of his having a very serious illness and his never being able to carry on his practice after that. I have been told that he was considered a very good physician in the community where he practiced. He belonged to the Methodist Church and was willing and glad to help in every way he could.

Timothy Arnold Pope was born in Otsego County, New York, on November 24, 1819, son of Jedediah and Lucy Angel Pope. When a boy of fourteen years, he moved with his parents to Chautauqua, in Chautauqua County, New York, in the extreme southwestern corner of the state. Two of his brothers were Jedediah and Gershom. The names of the other children in the family have not been learned.

In 1849 Dr. Pope was graduated in medicine from Western Reserve College, at Cleveland, Ohio, and in the following year he was married to Mary Abigail Howe, of Mentor, Ohio. Dr. and Mrs. Pope had four children, Laura Cornelia, Lucy C., Leon Dudley and Lida Edna. In 1941 the nearest living relatives of this pioneer couple were a niece, Mrs. Laura Barker, of Caledonia, Minnesota, and a grandniece, mentioned previously, Mrs. Eva Luella Evans, of Minneapolis.

Dr. Pope practiced medicine in Chautauqua County until 1854, when he moved with his family, in the exodus of hardy pioneers from the northeastern states into the Middle West, and settled in Houston County, Minnesota. They first made their home at Pope's Prairie, south of Caledonia, which had been named for Dr. Pope's brother, Captain Gershom Pope, who had preceded him into the county by a few months. The second brother, Jedediah Pope, also came into the region with his family in 1854.

In the spring of 1856 Dr. Pope took claim in section 13 of Yucatan Township and in that year was instrumental in having a post office established in the settlement that first was called Utica and later Yucatan. As noted earlier, he served as the first postmaster in Yucatan, but his duties did not prevent him from continuing his medical practice, managing his farm and serving as the first town clerk, a capacity in which he functioned for several years. In 1860 and 1861 he taught school in Sheldon. A year or so later he returned briefly to Yucatan, sold his farm and moved to the village of Old Houston. During his practice in that community he served as county coroner, in 1863 and into 1864, and acted as instructor in medicine to his nephew, John Edwin Pope.

Contemporary with Dr. Timothy A. Pope in Houston must have been Dr. P. T. Bowen. And, as has been noted, there were at the same time in various parts of the county, to name only those physicians who arrived prior to 1860, Drs. G. J. Sheldon, Alexander Batcheller, J. W. Albee, J. M. Veiling (Velling?), H. T. Fox, Charles Jenks, H. B. Train, T. R. Humphrey and perhaps H. B. Laflin.

Dr. Pope, evidently a true pioneer, in the early eighties left Minnesota for Iowa and later went to North Dakota, where he remained. He died at Grand Forks, on December 14, 1893.

De Costa Rhines was born on January 18, 1858, at Jackson, Michigan, the son of George Washington Rhines and Julia Lincoln Rhines, both of whom were natives of New York State. George W. Rhines was of Pennsylvania Dutch stock, his wife of English descent. Mr. Rhines served throughout the Civil War and his son, who was a very small child in 1861, has said that he first saw his father when the soldier returned home after the war.

De Costa Rhines attended the grade schools at Jackson and in 1882 was graduated from the local high school. In the summer vacations of this period he worked on the home farm; in the winters of 1880 and 1881 he combined his regular school work with the study of medicine under Drs. Towne and

Anderson of Jackson, so that by 1882 he was well prepared to enter the Hahnemann Medical College of Chicago, from which in 1884 he took his degree of Doctor of Medicine. Dr. Rhines' first medical practice followed immediately at River Junction, Michigan, where he remained only a few months before moving to Houston, in Houston County, Minnesota, in which state on August 18, 1884, he was licensed to practice, receiving certificate No. 937 (H). Houston was the scene of his activities for fourteen years. Politically independent, he identified himself throughout his career with the advancement of professional and community interests. For several years he was a member of the village council, for one year its president, and he also served as local health officer. In the late eighties he took Dr. Cassius S. Cranson, who previously had been in Sheldon, into association with him for about a year. Among the other physicians in Houston during his residence were Drs. H. P. Johnson and L. D. Onsgard (succeeding Dr. Johnson).

In 1898 Dr. Rhines took a postgraduate course at the Eye, Ear, Nose and Throat College and Hospital of Chicago and in that year, also, attracted by excellent opportunity in the village of Caledonia, he bought the practice of Dr. W. W. Freeman, who was moving to Grand Meadow. By 1899 Dr. Rhines had entered into his new field and here, as in Houston, he was a progressive physician and a leading citizen until his retirement from active practice in November, 1941, and his removal at that time to Owatonna, in Steele County, to make his home.

In Caledonia, Dr. Rhines served as local health officer and at one time as health officer for the Township of Brownsville also. He was county coroner in 1905 and in 1917 and, at the time of his leaving Caledonia, he again had been coroner for several years. He was president of the village council for two years; a member of the school board and of the commercial club; and during World War I he was chairman of the second, third, fourth and fifth Liberty Loan committees. He long has been a member of the Caledonia Chapter of the Masonic Lodge and of the Winona Consistory.

When the Houston County Medical Society was founded, at about the turn of the century, Dr. Rhines was a charter member, and he worked with the organization as it successively merged with the medical societies of Fillmore, Olmsted and Dodge Counties to form a four-county organization. At a meeting in Rushford of the Houston-Fillmore County Medical Society, in which he served as a censor, it was his privilege to propose as an honorary member his valued friend, Dr. Henry C. Grover, of Rushford, a veteran practitioner who had been "like a father" to him for years. Dr. Rhines has maintained membership in the Minnesota State Medical Association and in the American Medical Association.

On March 15, 1883, De Costa Rhines was married to Addie M. Peterson, of Jackson County, Michigan; their companionship has been unbroken. They have two children: Ray N. Rhines, manager of the Mechanical Department of the Northwestern Newspaper Company at Billings, Montana, and Hazell, at home, an able teacher, a graduate of the Winona Normal School.

Dr. Rhines has been distinguished by sound judgment in business. It has been a matter of personal pride and satisfaction always to own his own home. He has disclaimed hobbies, and it is obvious that his constructive work as physician and citizen has been his recreation as well.

(To be continued in the February issue)

EDWIN J. SIMONS, M.D.

President, Minnesota State Medical Association

President's Letter

PERHAPS, the first thing to be done in a letter such as this is to express a deep appreciation of the honor of serving as President of your State Medical Association. Then, too, with any such position come responsibilities which might be colossal and fearsome were it not for a feeling that you have always co-operated so wholeheartedly with the Executive Secretary and the personnel of his office, with the Council, with the Committee on Public Policy and Legislation, and with the other officers of the Association. It is this ever-present, harmonious, co-operative spirit on the part of all the physicians of the state which has given strength to the organization.

Also, initially, it is only fitting and proper to pay tribute to my immediate predecessor and those before him, to the members of the Council, to the various committee members, and to your other officers and State Office incumbents. Devotion to the duties of their several offices, self-abnegation, and perpetuation of high professional principles, have characterized their tenure in office. Always, the motivating force behind judgments made and actions taken by them has been the welfare of the patient-public and the best interests of the medical profession as a whole.

Thus, then, at this juncture, there is a sense of sincere gratitude, a realization of the challenge ahead, an appreciation of the abilities of preceding and present officers, and a feeling of loss that the enjoyable ties and associations at Council meetings and in other spheres of activity will slowly dissolve.

It is apparent that readjustment to peace is to be as hazardous as were the dislocations incident to war. Even now, integration of returning military physicians with civilian practice is our major problem. Its proper solution, mindful of needs and merits of our returning colleagues, is vital to the continued lofty level of civilian practice. This program is being jointly arranged by the Executive Secretary of the Association and the Director of Postgraduate Medical Education at the University of Minnesota.

Beyond this immediately pressing matter, two other questions present a challenge. The first requires that the standard of medical care not only be maintained but elevated proportionately with the remarkable scientific progress in various medical fields. And the second demands that medical minds be attuned to socio-economic changes in such fashion that from medical ranks will come the answer to trends toward government-controlled medicine. Preserving free choice of physician, the patient-physician relationship, quality of medical care, and the other basic features of the American System of Medicine, should be the keystone in any proposed new plan.

Bearing in mind these objectives, at this time when inventories are customary in the industrial and commercial world, an inventory of our accomplishments to date is warranted. The health of the civilians of the United States has never been better than it has been through the war years and now. Furthermore, military casualties, mortality and morbidity were never lower in any previous war than in American forces in the war just over. Thus, both civilian and military physicians can feel proud of the accomplishment of American medicine to date. This, however, should not lull us into a sense of complacency, but should spur us on to higher goals, including greater human longevity, still lower mortality, and continued advancement in all phases of scientific medicine.

Similarly, with all the public and political interest in health insurance and various forms of government controlled medicine, the Minnesota State Medical Association is keeping apace with social and economic departures in its Prepaid Medical Care Plan. Combined with this, undoubtedly will be evolved measures by which adequate, good, medical care will continue to be available to all of the people of Minnesota at a cost which they or the taxpayers can afford to pay.

So, with our house in fair order at the moment, with the objectives of the future clearly before us, let us continue working together in the same effective manner which has given us reasonable success in the past.

Edwin J. Simons

INCENTIVES IN PRIVATE PRACTICE AND STATE MEDICINE

LITTLE attention has been called to the fundamental differences in incentives under the systems of private medical practice and state medicine not only on the part of physicians but of patients.

In private practice the physician takes pride in his work. He strives to do his best in the making of a correct diagnosis and in prescribing the best possible treatment. Besides taking pride in his work, he knows that a medical practice is built up by the reference of new patients and by satisfied former patients. Satisfying patients is an art based on the rendering of thoughtful examination and prescribing. Some are lacking in the art to begin with and never acquire it. Some overdo the art and are weak in the application of scientific medicine. But, by and large, the physician has the incentive to give his best to his private patients. He charges what he believes his services are worth, and it is usually in line with that charged by his confreres. While he may adjust his charges one way or the other, depending on what he believes to be the financial status of the particular patient, his charges are as a whole rather uniform. He knows that overcharging will drive his patients away, whereas undercharging may give the impression of inferior service obtained.

The patient, on the other hand, seeks the services of a physician about whom he has heard a favorable report. And he seeks him generally because he is not well or at least thinks so. He is willing to part with a fee in order to obtain the advice he desires.

In state medicine, the physician's incentive is likely to be quite different, human nature being what it is. If he is paid a salary, he may still have the desire to retain that feeling of satisfaction from rendering his best, but his best is likely to sag if he sees little opportunity of obtaining advancement as a result of good work. If his financial compensation is not increased by the seeing of more patients, that incentive is gone. He will have little desire to accommodate patients as to time and place.

If the physician is compensated according to a fee schedule, the incentive will be present for unnecessary visits, and, if he collects for medicine prescribed, for useless medicine.

If, on the other hand, the patient is at liberty to visit a physician at any time of day or night at no cost to himself, he has no inhibitions on his demands for medical service, and the percentage of unjustified calls mount. Calls by neurotics would make practice unbearable. If the physician is paid under state medicine on a visit basis, there would be little incentive to discourage unnecessary visits.

Is it any wonder that in New Zealand where free physician service has been in existence in recent years and where any New Zealander may visit a physician as often as he likes and the doctor can collect a fee for each visit, that the cost has exceeded the calculated $5,000,000 a year by 50 per cent? This state of affairs is called racketeering. It is simply the inevitable result when people feel they can get something for nothing. Government leaders in New Zealand have reported that the present income taxes, which go as high as seven-eighths of all earnings, enable the Government to recover most of the money paid to such doctors. State medicine in New Zealand has proved expensive both from the government's and from the physician's standpoint. Consideration is being given to its termination. State medicine in the United States would result in the same experience.

THE PEPPER BILL AGAIN

THE Pepper Bill, as the Maternal and Child Welfare Act of 1945 is known, has been introduced in Congress and provides for complete medical nursing, hospital and dental care for maternity services and children up to the age of twenty-one, irrespective of ability to pay. The bill proposes to furnish this care essentially the way the EMIC program for GI wives and chillren has been carried out through state agencies. The bill provides for choice of physician, and the hysician may decline to care for the patient. Compensation would be according to a fee schedle or salary as determined in the states conerned. The cost will be met through federal taxtion.

According to the most recent publication *Briefs)* of the Maternity Center Association of New York, an organization devoted to promoting etter maternity care in the United States, the Medical Board of this organization, after due onsideration, has approved the Pepper Bill in rinciple and is making this opinion known to he Congressional committees concerned. They lo, however, make two important suggestions: (1) that the age limit be fourteen instead of wenty-one; and (2) that consideration be given o restricting the benefits of the services provided under the bill to those who cannot pay for adequate high quality care.

The Pepper Bill, as submitted to Congress, constitutes state medicine for obstetrics and pediatrics and for youth up to manhood and womanhood. The medical profession is opposed to the replacement of private practice including obstetrics and pediatrics by state medicine.

If the Pepper Bill is modified to apply to the medically indigent only, quite a different proposition is presented.

That a certain number of mothers and children lack medical and dental care is a fact. This is due to a variety of factors. Some cannot afford it. Others live in districts unable to support physicians and dentists. Some spend their income on less essential things. With some, the cost of catastrophic illness is entirely beyond their means without the aid of insurance. Hospital and medical prepayment insurance will do more and more as they expand to provide medical care for the low-income group and will lessen the number of families who could be classed as medically indigent.

No matter how much voluntary prepayment medical and hospital insurance expand, there will still be a medically indigent group. These are being provided for by numerous tax-supported and charity organizations, not to mention the free or reduced fee services rendered by physicians individually.

The actual need for greater assistance for this group is doubtless exaggerated by would-be reformers. Certainly, the need is not so great as to justify the entire socialization of obstetrics and pediatrics with the establishment of another bureau in Washington. Even if the Pepper Bill is modified to provide for the medically indigent alone, the question arises as to the use of federal funds for such a purpose. Meeting such a need by the local units of city, county and state is likely to be less expensive. After all, federal subsidies are raised by federal taxation and are not in the nature of a gift.

The care of mothers and children presents a strong emotional appeal. This does not mean that there should not be a realistic approach to the problem which is local and should be solved locally.

DR. SHOULDERS TO LEAD BATTLE OF FREEDOM

There is a splendid timeliness in election of Dr. Harrison H. Shoulders to presidency of the American Medical Association, for American medicine is facing the challenge of socialization, and Dr. Shoulders has been in the forefront of the fight against that hazardous challenge.

Leaders in the medical profession know the dangers invited by political control of medicine, however glibly its advocates dress it in words of innocence. As speaker of the AMA's house of delegates, and throughout his service in the Tennessee Medical Association, as member, secretary, and editor, Dr. Shoulders has led an uncompromising fight for the freedom of medicine from such political encumbrance, and he will bring to this new assignment the same unswerving defense of freedom's safeguard.

Dr. Shoulders will take office next year, but the fact doesn't abate the force of his immediate fight, and the American Medical Association's. They have mobilized for it; obviously are recruiting leadership of maximum stature, and command thereby the faith of the American public whose welfare is at stake. It is hardly likely that thinking American citizens will prefer political voices to authoritative, medical voices on a subject involving life and health. It is inconceivable that thinking citizens will permit subjection of MEDICINE to the principles of boondoggling, or assign it to the arrogant, untender mercies of bureaucracy.

Dr. Shoulders has earned the faith of his vast constituency, not only for professional skill, but for vision incorporating those standards and principles of medical freedom enabling American medicine to forge ahead in a field of science whose boundaries must remain beyond the reach of government dictation. As such a leader, his opinion will bear weight with the people. In this fight, his service again is to his country, no less than when he wore his country's uniform against another, external enemy.

The American Medical Association is to be congratulated for choice of such a leader; Dr. Shoulders for the opportunity conferred; the country for possession of such leaders for the defense of principle at home.—*Nashville Banner*, Dec. 6, 1945.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

NEW ERA IN VETERANS MEDICAL CARE SEEN

It is becoming increasingly apparent to politicians who would like to be on the receiving end of some pork-barrel doles relative to veterans hospital sites that times have changed and that the new Veterans Administration meant business when it announced a policy of situating veterans hospitals solely on the basis of what will best promote the health and rehabilitation of the veteran.

Both Major General Paul R. Hawley, Medical Director of the Veterans Administration, and his Chief, General Omar Bradley, are grimly insistent that areas that are medically strategic, not politically important, are to be selected.

In line with this policy, of the nineteen new hospitals providing for 11,100 beds to be available by June, 1946, thirteen are to be located near medical schools. This is intended to make available the part-time services of specialists where they will be most readily accessible—near teaching and more populous centers.

Minnesota Plans Shaping Up

A joint announcement last month by Dr. Harold S. Diehl, Dean of the Medical School of the University of Minnesota, and Mr. Carl D. Hibbard, regional Veterans Administrator, revealed a plan, one of the first of its kind in the country, under which University Hospital physicians will be sent to the Minneapolis Veterans Hospital. The revamping of the medical services there and the supplement of professional services to ease the physician shortage existing at the present time, will result in providing veteran-patients with medical care that will be on par with that offered in any private institution in the state.

In the deficiency appropriation bill before Congress, approved by the Senate last month, are included plans for a 200-bed veterans hospital in southern Minnesota, estimated to cost $2,655,701, to be used for tuberculosis treatment; and a similar sized hospital in Duluth, at an estimated cost of $2,497,751, for general medical and surgical treatment.

New Hospital Administrator Minnesota Man

Recently named administrative head of Veterans Administration hospitals for the entire country was Lt. Col. Harry E. Brown, who served for ten years prior to his being called to duty in January, 1942, as superintendent of Northwestern Hospital in Minneapolis. In addition to directing hospital planning and business administration, he will be in charge of selecting new hospital sites, acquisition of beds in civilian as well as Army and Navy hospitals and taking over Army and Navy hospitals declared surplus.

The majority of these institutions, as well as the new units being planned, are to be devoted largely to domicile the so-called "long stay" patients—the nervous and mental cases, the cardiac cases, the tuberculous and those requiring specialized services.

Outpatient Care a Local Problem

At the AMA House of Delegates session last month, Major General Hawley, speaking before the delegates, placed the responsibility for the development of a program for veteran outpatient service, satisfactory to physicians and the Veterans Administration, squarely up to the State Medical Societies.

Stressing the problem of outpatient care, Dr. Hawley stated that the Veterans Administration would like to have every physician in each community designated as a veterans physician. In this way, the veteran gets his medical care just as any other member of the community does—from a physician of his own choice, and not, as in the past, from one or two designated physicians in the community.

No set scale of fees is contemplated, Dr. Hawley said. The program is to be operated on the premise that these will vary with states and it will be the duty of the State Medical Societies to determine equitable fees in their respective states.

Welcome news to physicians is the promise that administrative work will be kept to a minimum by simplification of forms that have to be filled out. It is planned to assist the busy physician by staffing suboffices with clerical help to handle the bulk of their paper work.

At a meeting of the Council of the Minnesota State Medical Association on December 16, a committee was appointed to work with the Veterans Administration here to develop a plan for Minnesota that will meet with approval both of the Veterans Administration and the physicians in the State.

MINNESOTA CIVILIAN HOSPITAL FACILITIES UNDER SURVEY

Even as United States senators were readying themselves for passing, with relatively slight modifications, the original Hill-Burton Hospital Construction Bill, the governor-appointed members of Minnesota's Hospital Survey Committee were discussing ways and means to speed the state-wide survey that would make funds available for hospital construction here. The survey was directed into the capable hands of Dr. Viktor O. Wilson, Director of the Division of Child Hygiene of the State Health Department, under whose direction the Minnesota Hospital Licensing program has functioned remarkably well since its establishment by legislative act four years ago.

Supplementing the considerable data compiled on Minnesota hospitals under this program, are extensive statistics in the files of the executive office of the Minnesota State Medical Association as a result of on-the-ground surveys of health facility needs conducted by Minnesota physicians a year and a half ago.

Under the provisions of the Hill-Burton Bill, once the survey is completed, the state agency designated to handle the program would set up a plan for hospital construction designed to provide facilities on as wide a scale as possible. This plan would be submitted to the surgeon general for approval together with facts regarding financial sources available from state or local sources, which determines the extent of the federal grant.

To date some sixty communities are planning new hospitals or additions, involving an expenditure in excess of $40,000,000 for the next five years. Plans for these will go ahead even without federal aid. However, if the bill is passed, a large expansion to present plans is held likely.

Facts have come to light recently that certain ambitious public officials have grabbed at the chance to make headlines by importing, by invitation, personnel from the United States Public Health Service to conduct independent surveys of individual hospitals. This would certainly not appear to be in conformity with the bill which specifically provides for an over-all survey.

A PERSPECTIVE OF COMPULSORY HEALTH INSURANCE

President Truman's compulsory health insurance proposal fits perfectly with the social ideas of those who believe that government should undertake to protect all humanity against all the ills of existence at public expense. However, thoughtful people join the medical profession in viewing this whole idea of governmental supervision of medical care with a great deal of skepticism based on past performance in recent years of government intervention in many private fields. Indisputable evidence, demonstrated on many fronts, indicates that governmental bureaucracy tends to produce mediocre performance, and to discourage inventiveness and new ideas, all of which is inimical to scientific progress. American medicine, on the other hand, has achieved tremendously because every medical man is stimulated to do his very best by the prodding of his own conscience, by the constant competition within his own profession, by the knowledge that his earnings from his practice are not guaranteed by anybody and must be earned by his own initiative and skill.

While the matter of cost never seems to be given serious consideration in these days of billion dollar federal budgets, the fact remains, according to reliable medical statistics, that the President's proposed tax of four per cent on all incomes up to $3,600 a year to pay the cost of compulsory health insurance for everybody is in excess of what families are paying today for all they need of the very best medical care.

The matter could well resolve itself into less health at more cost if one is to judge by the results in nations where compulsory health insurance has existed for many years.

New Zealand Offers Typical Example

Take the case of New Zealand, where free medical service is provided for all its citizens. According to a report published in the *New York Times* for October 7, the increasing annual cost of medicine has been alarming the Health Department for the last three years. Because of widespread abuses, the government of New Zealand is seriously considering the discontinuance of the present plan whereby any New Zealander is permitted to consult any physician as frequently as he likes, and the doctor collects the fee for each visit from a government fund. Abuses cited include "overconsultation" and speedy examination of patients, some at a rate of twelve an hour.

New Zealand's experience would seem to indicate that when the so-called "financial barrier" between the patient and doctor is completely removed or reduced to negligibility, the patient will consult the doctor for the most trivial or imaginary complaints. As for the doctor, when the time spent in unnecessary medical work is added to the time spent in reporting services and claims for services to the central authorities, there is little time left for attendance upon the patients who really need extensive care and treatment.

Furthermore, during the period when a great many New Zealand doctors were still in the armed forces, payments to civilian physicians were fifty per cent higher than the five million dollars a year which the government calculated would cover the total annual peacetime cost of the program. It appears now that the government would like to place all physicians on the basis of a fixed annual salary or retaining fee.

Immediate Action Necessary

It seems safe to predict that the majority of the physicians returning from the service will join their colleagues on the civilian front to frown on President Truman's proposed plan because they have had enough government control for a while and want to be free to practice on their own. And what about veterans? Employed veterans with service-connected disabilities, who are already entitled to medical care, are certainly not going to look favorably on paying extra for help which they already rate.

This is no time to merely sit back with objections and rejections, however vociferously they are voiced. It is rather a time to mobilize all forces of organized medicine to speed the development of a specific national health program with emphasis upon the nationwide organization of locally administered prepayment medical plans sponsored by medical societies as approved at the House of Delegates of the American Medical Association last month.

The subcommittee of the Council on Medical Service and Public Relations appointed at that time to shape up a national plan should be expected to function without delay.

MEDICAL CONTINUATION COURSES

The University of Minnesota Center for Continuation Study has announced a series of courses for graduates of medicine whose plans for continuation education were interrupted by military service. The courses of study have been arranged for physicians who plan to accept an association with a specialist, obtain a residency, prepare for American Board examinations or return to practice.

Classes will be taught at the Center for Continuation Study, Medical School, University of Minnesota Hospitals, Minneapolis General Hospital, Ancker Hospital, Saint Paul, and affiliated teaching institutions.

Distinguished teachers from other medical centers will join the faculties of the Medical School, other University Departments and the Mayo Foundation to teach these courses, scheduled to begin January 4.

The following courses will be offered, with others to be announced later:

Continuation Course in Medicine—January 4 to March 30, 1946

Continuation Course in Basic Sciences—January 4 to March 30, 1946

Continuation Course in Otolaryngology—January 14 to 18, 1946

Continuation Course in Pathology of Diseases of the Skin—January 21 to February 20, 1946

Continuation Course in Hospital Administration—January 21 to 25, 1946

Continuation Course in Basic Sciences (concluded)—April 8 to June 29, 1946

Continuation Course in Surgery—April 8 to June 29, 1946

Anyone interested in securing further details may address correspondence to the Center for Continuation Study, University of Minnesota, Minneapolis 14, Minnesota.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary
230 Lowry Medical Arts Building
Saint Paul, Minnesota

Minneapolis Woman Ordered to Serve Two-Year Sentence for Narcotic Law Violation

Re State of Minnesota vs. Florence B. Brooks

On November 7, 1945, the Hon. Paul S. Carroll, Judge of the District Court of Hennepin County, revoked a stay of sentence entered on December 14, 1944, and ordered Florence B. Brooks, thirty-eight years of age, 1819 Bryant Ave. No., Minneapolis, taken to the Women's Reformatory at Shakopee, to serve a sentence of two years. The defendant entered a plea of guilty in the District Court of Hennepin County on December 14, 1944, to an information charging her with the crime of illegally possessing narcotic drugs. She had been arrested on November 4, 1944, by agents of the Federal Bureau of Narcotics immediately after having left the office of a Minneapolis physician who had furnished her with sixty ¼-grain Morphine Sulfate hypodermic tablets and twenty-five ½-grain Morphine Sulfate hypodermic tablets.

At the time Judge Carroll stayed the execution of sentence, the Court ordered the defendant to take treatment for her drug addiction. The treatment lasted three days and the defendant soon reverted to the use of various derivatives of opium. Through the excellent work of Mr. Howard R. Hush, Chief Probation Officer of Hennepin County and Mrs. Elvera M. Springer, Probation Officer, Mrs. Brooks was brought before Judge Carroll for violating the conditions of her stay of sentence, with the result that on November 7, 1945, Judge Carroll made an order revoking the stay. The defendant has been taken to the Women's Reformatory where she is now serving her sentence.

Fake Doctor Sentenced for Hospital Robbery and Car Theft

Re: State of Minnesota vs. John R. Kahl
Re: United States of America vs. John R. Kahl

On September 18, 1945, John R. Kahl, twenty-five years of age, 1610 Roblyn Avenue, Saint Paul, Minnesota, was sentenced by the Hon. Robert V. Rensch, Judge of the District Court of Ramsey County, Minnesota, to a term of one to ten years at hard labor in the State Prison at Stillwater, Minnesota. Kahl had pleaded guilty on that date to an information charging him with the crime of grand larceny in the first degree, following the theft by Kahl of money and jewelry in excess of the value of $500 from physicians and surgeons at a Saint Paul Hospital.

On October 9, 1945, Kahl was brought back from the State Prison at Stillwater, and taken to the United States District Court in Minneapolis where he entered a plea of guilty to three indictments charging Kahl with unlawfully transporting, in interstate commerce, three stolen automobiles. On the first charge Kahl was sentenced by the Hon. Matthew M. Joyce to a term of five years in a prison to be designated by the Attorney General of the United States, the sentence to commence after Kahl has served his Stillwater Prison sentence. Judge Joyce also sentenced Kahl to a term of three years for the second case, this sentence to commence immediately on the termination of the five-year sentence also imposed by Judge Joyce. On the third charge, Judge Joyce suspended the imposition of sentence for three and one-half years, Kahl to be on probation following his release from Federal Prison.

Kahl has a long criminal record dating back to when he was ten years of age, at which time he was first arrested at Boone, Iowa, for theft from a doctor's office. In September, 1933, Kahl was sentenced to the Red Wing Training School for burglary committed in Saint Paul. In June, 1935, Kahl was again returned to Red Wing on a charge of burglary. In September, 1938, Kahl was indicted by a Federal Grand Jury in Saint Paul on two charges, the first one alleging that Kahl stole a letter from a United States mailbox and the second one charging Kahl with escaping from the Ramsey County Jail where he was held while awaiting action of the grand jury. Kahl was given a total sentence of six years by the Hon. Robert C. Bell, Judge of the United States District Court. Kahl was first taken to the Federal Reformatory at El Reno, Olahoma, but was transferred from Leavenworth to the Federal Prison at Sandstone, Minnesota, where he served until June 6, 1945. Following his release, Kahl obtained work as an orderly at a Minneapolis hospital. This undoubtedly gave him the background for his entry to the hospital in Saint Paul where he committed the theft that led to his ten-year Stillwater sentence. Kahl has no training or education in the field of medicine.

IT'S NOT A CONSPIRACY

The idea persists in the minds of a few irreconcilables in the medical profession that Blue Cross plans are engaged in a sinister plot to grab control of the profession. Some even believe that hospital administrators are using Blue Cross as a tool to gain this evil end themselves.

For example, a recent issue of the *Bulletin* of the Winnebago County (Illinois) Medical Society publishes this statement attributed to an insurance executive: "I have made a rather comprehensive study of the Blue Cross history in an attempt to ascertain their present and ultimate goal, and it has become quite obvious to me that they intend to dominate not only the field of hospital insurance but also the field of surgical and medical care eventually."

In the same article, the past president of a state medical society is quoted as saying: "As between domination by the federal government and domination by hospital administrators, I think I should prefer the former. Unless we are very careful indeed, we are apt to find hospitals dictating the practice of medicine."

Of course, no one can say what is in the mind and heart of every last hospital administrator and Blue Cross executive in the country, and it may be that there are a few whose ambitions soar unreasonably toward widening powers. But every informed person will recognize as fantastic the implication that there is any general plan or intention in this direction. Unfortunately, many doctors who read statements like these in their medical society bulletins are unable to distinguish between fact and fabrication; they have had neither the time nor the interest to know better. Instead, they accept this fiction as truth and pass it on, thus unwittingly contributing to the conflict and suspicion that still delay decisive action toward a national voluntary health plan.

Publication of this fairy tale is as harmful as it is irresponsible. It ought to be stopped.

—*Modern Hospital*, December, 1945

Minneapolis Surgical Society

Stated Meeting held October 4, 1945

The President, Robert F. McGandy, M.D., in the chair

EMBOLISM OF THE RIGHT FEMORAL ARTERY

Report of Case

H. E. HOFFERT, M.D.
Minneapolis, Minnesota

This report is that of a white man, sixty-five years of age, who has had a long cardiac history. As a youth he had had rheumatic fever which left him with a double mitral lesion and which caused him to limit his activity to some extent thereafter. Twenty years ago on the advice of his physician he had begun taking 1 grain of digitalis twice weekly, a practice which he followed continuously without further checkup. Two years ago he suffered what was assumed to be a mild cerebral accident from which his recovery was complete, without seeking medical advice. He has been aware of irregular heart action for the past ten or twelve years. During the past year he had been feeling unusually well and had been working daily as a salesman for a paper supply company.

His present complaint began on February 18, 1944. For a week preceding he had had an upper respiratory infection but arose on this date feeling very well. At 8:40 that morning while shaving, he became aware of a tingling sensation in his right foot which was followed shortly by a persistent agonizing pain in his foot and lower leg. He was unable to move the foot on the ankle and could not secure any relief by changes of position.

He was seen at 9:30 a.m. when examination revealed an irregular heart with a pulse deficit of 18, blood pressure 160/90. The right foot and distal half of the leg were blanched and cold. The dorsalis pedis, ankle and popliteal pulsations were absent and the femoral pulse diminished as compared with the opposite extremity.

A tentative diagnosis of embolism of the right femoral artery was made and arrangements for transportation to and admission in Asbury Hospital carried out. He was given morphine sulfate grain ¼ from which he secured only partial relief.

Upon his admission to the hospital it was noted that the initial pallor of the lower leg and foot was beginning to be replaced by cyanosis and the femoral pulsation was still less prominent.

Laboratory studies showed his hemoglobin to be 105 per cent, white blood count 12,500 and urinalysis negative. An electrocardiogram was interpreted as showing an auricular fibrillation, myocardial damage and coronary disease.

He was seen in consultation with Drs. A. E. Cardle and S. R. Maxeiner, and immediate surgery was advised.

Operation: 500 c.c. of citrated blood and 100 milligrams of heparin for intravenous administration were in readiness.

Under local infiltration anesthesia an incision 4 inches in length was made directly over and parallel with the proximal portion of the right femoral artery. The artery was exposed and mobilized. There was no visible or palpable evidence of pulsation. A small longitudinal incision was made in the vessel after two small rubber-covered clamps had been passed loosely on the artery above and below the site of incision. A size 12 French catheter attached to a 20 c.c. syringe was then passed gently into the artery, distal to the opening, and aspiration showed no evidence of occlusion below this point. The catheter was then passed proximally, aspirating and advancing it cautiously. On the third attempt an embolus 3.5 inches in length was withdrawn and its removal was immediately followed by a very forceful gush of blood, which was controlled by gentle pressure with the rubber-covered clamp. The incision in the artery was closed using interrupted sutures of fine silk, care being exercised to avoid penetration of the intima. The clamps on the vessel were removed and it began to pulsate actively. It was kept under observation for eight to ten minutes, and after no diminution in pulsation occurred, the wound was closed and a pressure dressing applied.

Postoperative medication consisted of morphine sulphate grain 1/6 as indicated for pain, papaverine grain ½ every four hours, and heparine 20 milligrams intravenously every four hours for forty-eight hours, which resulted in a venous clotting time of 9 minutes and 30 seconds at the end of 24 hours, and 20 minutes at the end of 48 hours. Dicumerol 300 milligrams was given orally on the first postoperative day and 200 milligrams on the second which resulted in a reduction of the prothrombin time to 20 per cent of normal on the third postoperative day. During the following seven days this reduction was maintained by the additional administration of 100 milligrams of dicumerol on two occasions, daily prothrombin determinations being done.

The postoperative course of this patient was entirely uneventful. Six hours after operation the extremity was warm, the cyanosis was clearing and the popliteal pulsation was full and strong. The dorsalis pedis and tibial pulsations were present twenty-four hours later. His wound healed primarily and he was discharged walking on the fifteenth postoperative day.

Since operation he has remained under the constant care of Doctor Cardle and has been carrying on his work as before.

On September 23, 1945, nineteen months after his embolectomy, this patient suffered another arterial occlusion in the right lower extremity. He did not report this incident until fifteen hours later and by that time the appearance of the leg was such and the condition of his heart so grave that attempted embolectomy was not deemed justifiable. He is at the present time in Asbury Hospital undergoing a tourniquet amputation of the right leg. His condition at the present time is rather poor.

Discussion

Dr. Daniel MacDonald: How soon after initial symptoms was the operation performed?

Dr. H. E. Hoffert: Symptoms started at 8:40 in the morning and the operation was begun at 2:40 in the afternoon.

Dr. McDonald: How long was dicumerol kept up?

Dr. Hoffert: He received 300 milligrams on the first day, 200 on the second, and the prothrombin time was reduced to 20 per cent of normal. Daily prothrombin time was never above 20 per cent of normal. Only 200 additional milligrams of dicumerol were given during the subsequent week. After that it was discontinued.

LUMBAR SYMPATHETIC BLOCK AND THAT POSTPHLEBITIC LEG

H. O. McPHEETERS, M.D.
Minneapolis, Minnesota

Doctor McPheeters presented a paper on "Lumbar Sympathetic Block and That Postphlebitic Leg."*

He discussed the theory and principle of the lumbar sympathetic block and how it should be of value as an additional therapeutic aid in the healing of the chronic trophic skin conditions that follow in the wake of the deep thrombophlebitis of the lower extremity.

The Ochsner method was advised and 1 per cent novocaine was the solution injected. It was not advised as a permanent cure, but only as a helpful adjunct in the healing of the otherwise intractable and chronic trophic state of the lower leg.

Four separate case reports were given, demonstrating the help and value of the lumbar sympathetic block for this condition.

Discussion

Dr. F. R. Hirshfield: Isn't there potential danger of an embolism there when you relax the vessels of the extremity by blocking?

Dr. McPheeters: Therapeutically yes, but as Doctor Hoffert suggested in his case, all cases should be given heparin followed by dicumerol to reduce prothrombin time to 20 per cent of normal. Therapeutically you are supposed to increase the possibility of embolism, but practically you do not. I merely mentioned the deep femoral ligation. This treatment of thrombophlebitis has spread throughout the country and I predict it will recede to the background in less than ten years.

Dr. Earl C. Henrikson: I wonder whether it would not be better to get the patients up the fourth or fifth day, even if signs of phlebitis are developing, since by so doing we are dilating the blood vessels and stimulating the circulation by physical exercise which is what we hope to do when we do a therapeutic block. I know that most surgeons have felt that the patient would have to stay in bed longer when developing a phlebitis rather than that they should get up earlier.

Dr. McPheeters: During my visit in Brooklyn last winter I heard prominent obstetricians say they got their postpartum patients up on the fifth day. Some surgeons urge their appendectomy patients to get up on the second day postoperative.

Patients sometimes have more chance of dying by lying in bed. Their chances are better by getting up. My routine is to apply hot wet packs at a temperature of 130 for four hours at a time. The patient then is up and walking about one-half hour followed by the application of the hot wet packs.

THE TREATMENT OF NEUROSURGICAL CASES IN AN OVERSEAS HOSPITAL

WALLACE P. RITCHIE, M.D.
Saint Paul, Minnesota

The treatment of cases in the Army given by any one doctor or group of doctors depends to a great extent, not only on the situation and type of hospital in which the doctor is located, but also on the tactical situation presenting itself.

It will be well, therefore, to briefly describe the locations in which the 26th General Hospital was situated. The two locations in which the 26th General Hospital found itself were very different, not only as to housing, equipment, and place, but also as to the tactical problems.

While in Africa, the hospital was set up during the last six weeks of the Tunisian Campaign, the Sicilian Campaign, and the early part of the Italian Campaign. At no time was the actual front less than 150 miles away and in only a few instances did cases arrive without primary treatment. The casualties for the most part were ground force troops. A policy of evacuation was such that patients were not held for more than thirty to sixty days.

The Italian setup was different in many ways. The situation was more stable. The hospital was one of six assigned to the 15th Air Force, which comprised from 90,000 to 120,000 personnel and was large enough so that patients would not have to be evacuated to make room for other patients. The number of casualties arriving at one time was never large, and as a general rule no patient suffered because of lack of time.

It was an ideal location, as not only were casualties treated primarily (although small in number), but definitive treatment could be carried out. Furthermore, all of the diseases and conditions usually arising in a community of over 100,000 were encountered.

The equipment furnished by the Army was entirely adequate. In the early stages an electro-surgical unit, brought over by the unit, was the only one functioning in Africa, but it was not long before others became available.

---

*See page 43 for complete paper.

In Italy, we were furnished a quantity of fibrin foam and fibrin film.

Fibrin film was used in ten cases and the only observed results were not satisfactory. It had been advocated especially as a covering for dural defects. We used it only once for this purpose. The wound became infected. The film extruded and the patient developed a meningitis. In eight other instances it was used as a covering of a nerve and in one as protection of a tendon. The latter became infected. This was not the real reason for our discouragement in its use.

A patient, whose slide you observe, was shot in the upper arm by a rifle bullet, on October 2, 1944, suffering a complete section of the ulnar nerve. On October 23, 1944 (21 days later), the left ulnar nerve was sutured and a cuff of fibrin film placed around the nerve. On February 26, 1945 (125 days later) he returned for examination, and there was definite evidence of regeneration. There was, however, such a large mass of scar tissue beneath the operative scar that the wound was reopened and the scar removed from around the nerve. Shortly after this we received information that others had also noted the excess of scar tissue after the use of fibrin film.

Fibrin foam, however, lived up to its predictions, as being an ideal hemostatic. We used it in about fifteen instances and found it controlled bleeding well. In one instance it was packed in the lateral sinus. In another, it was packed into a rent in the dura in the region of the cribiform plate, as exposure was inadequate for suture. Cerebral spinal fluid leakage immediately ceased and no rhinorrhea developed. Lyle Hay controlled severe bleeding from an ulcerated rectal mucosa by packing the foam against the bleeding area. Its use for controlling liver and kidney hemorrhage is easily visualized.

The penicillin supply was adequate and was used to advantage in abscess cavities and in three of our patients who developed meningitis. Penicillin used in strength of 1,000 units per c.c. 10,000 units every six hours (sixteen times in one, ten times in another, and seventeen times in the third), undoubtedly aided in recovery. In one instance meningitis developed in spite of the use of intramuscular penicillin for six days prior to the onset of his illness.

Wounds of the Head

The principles laid down by Cushing, in 1917, of thorough debridement of penetrating wounds of the brain, was the foundation of the treatment of this type of wound.

Peter Ascroft, of the British Forces, was the first person to have a wide experience in this type of surgery, and his early reports aided the Americans in establishing their policies. At the very outset it was found that an early inadequate debridement was not as valuable a late adequate procedure, although the best results were obtained by an early operation. A delay of even seventy-two hours was deemed advisable if facilities in the form of equipment and personnel were not adequate before that time. With our system of Auxiliary Surgical teams and well staffed evacuation hospitals close to the point of injury, such a lapse of time was rarely necessary. In the particular instance of our hospital, the interval between time of injury and operation was on an average eight hours.

The cases of penetrating wounds we received were the ideal type to handle, as they occurred in men who were relatively clean to begin with and they were flown directly to a field only twenty minutes from our hospital.

The procedure in handling a penetrating wound of the brain was as follows: As soon as admitted, the patient was examined for shock and hemorrhage. If he was in good condition, he was taken to the x-ray room where x-rays were taken. Stereoscopic films are a valuable aid in locating bone chips. The patient was then as a rule placed in bed where he was given a chance to stabilize himself from the physical and mental excitement of the last few hours. At the outset we felt it important to rush the patient to the operating room but in only exceptional instances, when hemorrhage is uncontrolled, is this necessary.

After this stabilizing period of a few hours has passed the patient is taken to the operating room.

The choice of anesthesia is variable among the surgeons. Local anesthesia, except in the deeply comatose patient or the extremely co-operative patient, was never very satisfactory in my hands. We frequently used pentothal but in several instances were disturbed by severe laryngeal spasm, which required redraping. As a general rule, we used intratracheal anesthesia in all but the most simple procedures.

The wound edges were excised, a fundamental principle in the treatment of all war wounds. A thorough debridement of all the missile tract was then carried out. In our cases craniotomy was never necessary. Adequate exposure of the brain tract could be obtained through enlarging slightly the entrance defect. It was seldom necessary to enlarge the defect already present in the dura. The most important step was the removal of all bone fragments. Aschcroft demonstrated at an early stage that retained bone was the chief factor in the formation of abscesses, while retained metal fragments had little influence on the development of abscesses. This is done gently with the sucker. Occasionally a large fragment of bone plugs the missile tract, and after its removal necrotic brain, blood clots and small bone chips will gush forth. It is well to count the bone chips when removed, to check with the number seen at x-ray. The tract is cleaned down to the deepest bone fragment. As a rule, the metallic body is deeper. It is a question whether further debridement beneath the last bone fragment is necessary.

The ideal is closure of all layers. Frequently the dura cannot be closed. If closure is impossible, a free or a flap graft of the aponeurosis aponeurotica is the ideal. The exposure is seldom large enough to use the outer layer of the dura. Leonard Titrud used it to good advantage in one instance in which a craniotomy had been performed. Preserved and fresh fascia lata grafts have been used. The frontalis muscle was used frequently in frontal tears, where it is extremely difficult to suture the dura, particularly on the inferior surface of the frontal lobe.

As a rule the scalp could be closed, although relaxing incisions and flaps were occasionally used.

The postoperative care of these patients presents nothing of special interest. As examples of penetrating wounds, I present two cases with slides.

Case 1.—This boy, W. I. A., was hit at 1230 hours by flak which entered the left parietal region and came to rest in the right temporal region. He was admitted to the hospital four hours later, at which time he was deeply comatose. Three hours after admission (seven hours after injury), the tract was debrided and the foreign body removed as you will note in the slide. Then he regained consciousness, he had light perception in the right eye, but no vision in the left eye. Five weeks later (after having meningitis), his vision gradually returned.

Case 2.—This case represents an important point, namely, that all penetrating wounds should be explored regardless how small they are. He was hit by flak at 1300 hours. He was knocked down and thought he was unconscious for a few seconds. He was rather drowsy when observed at a station hospital. Because the wounds seemed so small, they were cleaned superficially. Ten days later he was admitted to our hospital complaining of headaches, and with a choked disc. The point of entrance in the bone was only a few millimeters in diameter, but the defect in the dura was 2 cm. in diameter. As soon as the dura was retracted, about 10 c.c. of blood and necrotic brain gushed forth. The tract was gently debrided to a depth of four centimeters, and the wound closed. His recovery was uneventful and he was later returned to full duty.

There were all gradations of severity between these two types. Those treating ground force troops observed more severe wounds than were observed in the air force.

The early complications arising from penetrating wounds were herniation of the brain with resulting cerebral fungus, abscess, meningitis, rhinorrhea, and otorrhea. Fortunately, we had little experience with these sequlae, mainly due to the fact that our series was small. In thirty-two cases of penetrating wounds observed in Africa, three developed brain abscesses. In thirty-one cases of penetrating wounds in Italy, three developed meningitis and one a brain fungus. Only one of these seven died, a patient with a brain abscess.

A brain abscess developing from such a wound is different from those that develop from otologic or sinus infections, mainly in that there is an open tract already outside. As a rule, opening the dura and tract with subsequent washing of the abscess cavity with penicillin will effect a cure. Two of the three abscesses observed in Africa were enucleated in toto, one by Titrud and one by French. The other patient died twenty-two days after injury, after aspiration of the abscess and debridement of the fungus.

I do not have the statistics for the development of brain abscesses, but I do know that their incidence decreased a great deal as time progressed. The results of our two cases were excellent with their removal in toto, but good results were reported by aspiration and tube drainage of the abscess cavity with instillation of penicillin.

The development of a cerebral fungus was a dangerous complication. They were of two kinds, acute and chronic. The acute were usually due to an early edema, and receded without specific treatment. The chronic were more difficult to care for, but were usually due to some disturbance deeper within the brain substance such as an abscess around bone fragments or a hemorrhage. They would not disappear until the underlying disease had been eradicated. Fortunately, we had only two cases in our group. One died with an underlying abscess and the other receded by itself.

The low incidence of meningitis, three in sixty-five cases of penetrating wounds, was no doubt due to early debridement. Two of these were due to other factors, infected fibrin film and faulty technique in one, and cerebrospinal fluid drainage in the other. The third was due to a delay in debridement, seven days after wounding. It is interesting to note that all three individuals developed meningitis in spite of their having had adequate doses of penicillin. As has been stated, they were all treated with intrathecal penicillin and two recovered. The cause of their meningitis was eradicated at the same time, but it was our impression that penicillin did aid in their recovery.

Only one case of persistent rhinorrhea was observed. This was surprising, as there were many frontal depressed fractures caused by crash landings, in which the dura in the region of the crista galli was torn. In several instances fibrin foam was packed into the region. Flaps of frontalis muscle were particularly helpful in closure of these wounds. In the one persistent case, a fascial graft was used for covering the defect.

It was surprising to us that intracranial hemorrhage did not play a greater role in penetrating wounds. Shoreston stated that there were only eighty-three cases in 2,000 in which an intracranial hemorrhage played an important role. It was interesting to note in cases in which the missile passed through the brain hitting the skull on the opposite side, that the hemorrhage was frequently on that side, namely, the side opposite the entrance. The repair of cranial defects was not, as a rule, a procedure for overseas installations. However, it was found advisable to perform cranioplasties in several instances. Tantalum was not available. Free bone grafts were used from the ileum or from the outer table of the skull, as demonstrated by the following slides.

Naturally, and particularly at the outset, the main interest was the penetrating wounds of the brain. We did have, however, many closed wounds of the head and depressed fractures which present no special featues.

Only three brain tumors were operated upon during our service. A large astrocytoma was partially removed in one instance. A cerebellar medulloblastoma was removed in another. The third case was a large ependymoma of the lateral ventricle.

As in all services, unusual cases present themselves. The following case was interesting:

A thirty-one-year-old soldier, with two and one-half years of service, had been well until November 1, 1942, when he developed a headache and blurring of his vision, after a severe sandstorm near Benghasi, Lybia. He soon recovered, but had intermittent headaches for the next eleven months. In December, 1943, he had chills and fever, and he was told that he had malaria. At this time his headaches became severe. On admission to our hospital, there was a two diopter choke of both discs. There was a slight right 6th crania nerve paresis.

X-ray examinations is as demonstrated on the slides. On January 19, a right transfrontal craniotomy was performed and a large cyst was demonstrated beneath and lateral to the optic chiasm. The cyst was evacuated and subsequent microscopic inspections revealed a cysticercus cellulosa. His post-operative course was uneventful. Nine months later he was reexamined and found to have performed full duty and had no complaints.

It is impossible to discuss the posttraumatic state here. Suffice it to say, it was a great problem and the will to return to duty was a great factor in the ultimate well-being of the patient.

I am unable to give the full statistics of our head injuries but I do have the data extending from January to October, 1944, ten of the seventeen months of activity. Of the twenty-seven patients with penetrating wounds, eight returned to duty, fourteen were returned to the U. S., and three died. Of eighteen patients with depressed fractures thirteen returned to duty, five were sent to the U. S., and none died. Of 137 patients with closed wounds 102 returned to duty, seventeen to the U. S., and five died.

Of 180 cases of all types, 68 per cent returned to duty, 28 per cent were sent to the U. S., and 4.5 per cent died.

The mortality of our penetrating wounds was approximately 19 per cent.

Nerve Injuries

At a neurosurgical conference in Florence, it was stated that the most pressing problem presenting itself to the conference was that of injuries to the peripheral nerves. May I present to you our experience with these injuries.

Both in Africa and in Italy we observed 445 patients with peripheral nerve injuries. One hundred and nineteen of these cases were operated upon, there being thirty-nine nerve sutures.

Factors which included difficulty in evacuation and satisfactory control of infection prompted an early repair of severed nerves.

Seventy-five per cent of the nerve lesions were in the upper extremities and the ulnar nerve was most frequently involved.

Penetrating wounds caused 79 per cent of the lesions.

Forty-three per cent were judged to be complete lesions at the time of the initial examination.

The average time of beginning recovery in the complete lesions not operated upon was thirty-four days. The ulnar and median nerve recovery was somewhat less than this period and the radial, femoral, and tibial was slightly more.

As time went on the flexible rule was that if recovery or improvement did not take place in four weeks in the ulnar, median, and musculocutaneous, six weeks in the radial and seven to eight weeks in the peroneal nerves, they should be explored provided, of course, the wounds were in a satisfactory state.

Incomplete lesions were explored if they showed no improvement on an average of forty-three days after injury.

Operations.—One-hundred and fourteen operations were performed of which thirty-nine were sutures, two autogenous nerve grafts, and seventy-three neurolyses. As a general rule, the gross reaction from the original injury had disappeared by four weeks. The scar present was firm and not edematous. Cultures were negative. Microscopically, there were a few giant cells and lymphocytes present but no evidence of acute infection.

There was one postoperative infection. Fibrin film was used in some instances as a cuff but was discontinued due to a very apparent increase in late postoperative reaction.

Early Results and Disposition of Cases.—None of the nerve sutures revealed any functional return prior to disposition from this hospital.

In a number of instances in which neurolysis was performed there was a rapid return of sensation and motor power. This was not always true as in two cases there was definite subjective and objective evidence of improvement in the first three or four days and then a return of the original condition with no further improvement at the time of discharge.

There were thirty-one cases of painful nerve lesions. Seven of these were sensory nerves. Fourteen of the twenty-four motor nerves involved were the sciatic or tibial or peroneal nerves. They all complained of severe pain in the foot, except one in whom there was a burning pain down the leg. This was the only one whose pain was relieved spontaneously (thirty-one days). In the lower extremity, the pain involved for the most part the plantar aspect of the foot. In the majority of cases, in which the nerve was demonstrated at operation, the nerve had been definitely struck by the missile.

The usual time interval for the onset of the pain was ten to fourteen days. Frequently as motor and sensory power increased, pain occurred. Sympathetic block gave the best relief in two brachial plexus injuries. One was permanently cured by novocain block alone and the other by sympathectomy.

Ten patients were relieved temporarily by sympathetic block. Two were not relieved.

Seventeen neurolyses were performed. All of them were relieved of their severe pain.

Late Results.—Follow-up records were obtained in 53 per cent of all the cases, operated and unoperated. Adequate follow-ups were received from twenty of 74 per cent of those operated upon. The follow-up interval ranged from six months to one and one-half years.

Summary

In six months five showed partial return; in one year ten more showed partial return. If there was no return in one year no improvement could be expected. It

"Smoothage" IN THE CONSTIPATION OF PREGNANCY

The constipation frequently encountered during pregnancy, due to pressure of the fetus on the pelvic bowel, lack of exercise, and restricted diet, is alleviated by Metamucil.

The Smoothage of Metamucil encourages easy, gentle evacuation. It does not interfere with the absorption of vitamins or other food factors:

METAMUCIL *is the registered trademark of G. D. Searle & Co., Chicago 80, Illinois*

RESEARCH IN THE SERVICE OF MEDICINE

(Continued from Page 70)

did take one year before recovery took place in peroneal and radial nerve sutures. In fifty-two neurolyses, in six months, eighteen showed partial recovery and four no recovery. In one year twenty-eight more showed partial and two no recovery.

There was a definite relationship between preoperative interval and the number showing recovery in both nerve sutures and neurolyses. Ulnar and median nerves seem to recover fastest. Practically all patients in whom recovery took place experienced associated pains and hyperesthesias in the cutaneous nerve distribution. Paresthesia was not a prominent symptom.

Discussion

Dr. William Peyton: I congratulate Doctor Ritchie on this very excellent summary of his experiences in the war.

We have had a little fibrin foam for experimental purposes and found it most useful in controlling bleeding from the pituitary fossa after removal of pituitary adenomata. Fibrin foam and thrombin placed in the operative defect and left there completely controlled all oozing of blood which is so essential for uneventful recovery in these cases. I regret very much that we no longer have any fibrin foam available for this purpose.

The difficulty seems to be that in peacetime there is not a constant and sufficient amount of human blood being processed for the preparation of this product. Whether or not it will be available for general use is uncertain, but at present, prospects for its availability, do not appear to be very favorable.

In speaking of repair of skull defects, Doctor Ritchie said he had used a bone graft of the outer table of the skull instead of the more generally used tantalum, which was not available to him. The outer table of the skull makes a very satisfactory closure of small defects. The objection that has usually been made to the use of the outer table of the skull does not obtain with the technique employed by Dr. Ritchie. It has been the custom to remove these grafts with an osteotome and hammer. This procedure is traumatic to the intracranial contents and therefore objectionable. Doctor Ritchie showed in the illustrations (but he did not stress it) that he removed these grafts by sawing off the outer table with a Gigli saw, so that this objectionable trauma is entirely avoided.

Of course, tantalum can be used. It is certainly the best material for repair of large cranial defects. We have used it. The plate can be cut and properly shaped at the operating room table, unless the contour of the defect is complicated, as is the case where the superciliary arch is to be reconstructed.

Doctor Peyton then showed some lantern slides of some cases of head injury.

The first case was that of an aviator who, on February 25, 1944, had a large piece of flak enter his right temporal region. It passed to the left and slightly downward so that on reaching the midline it passed through the sphenoid sinus, entered and lodged in the left cavernous sinus where it injured the left internal carotid artery. A carotid-cavernous fistula was thus produced on the left side. On regaining consciousness, six days after the injury, he heard a swishing noise in his head and this remained until the day before he was seen by Doctor Peyton (July, 1945) when it suddenly stopped and he developed a very severe headache. This bruit had been noted by all previous medical examiners and a diagnosis of carotid-cavernous fistula made.

On examination there was exophthalmos of the left eye and a left sixth cranial nerve paresis. There were some enlarged veins in the left sclera and the retinal veins were engorged. Visual acuity was normal. No bruit was audible. He was seen again one week later when there still was no bruit and no symptoms except some diplopia due to the sixth nerve paresis.

It is obvious that the day before this man was seen, or seventeen months after his injury, a spontaneous occlusion of the fistula had occurred by clot formation or thrombosis. The patient was reassured that a spontaneous cure had now occurred.

The symptoms, physical findings and pathologic changes in carotid-cavernous fistula were then discussed. Its treatment by ligation of the internal carotid artery in the neck or by packing the internal carotid artery with muscle strips, or by ligating the internal carotid in the neck and occluding it above the cavernous sinus with silver clips was illustrated by cases briefly reported.

Dr. L. H. Fowler: I cannot add anything to the scientific discussion because Doctor Ritchie has covered the subject so thoroughly. I do want you to know, though, that I appreciate his efforts and his work. You can tell from his presentation the fine work he has done for three and one-half years as Chief of the Section on Neurosurgery of the 26th General Hospital. He was not only most skillful and tireless in his work, but one of the most popular—if not the most popular—men in the outfit, always on the job, always co-operative, always a gentleman and a scholar.

Capt. Nathan Plimpton, M.C.: I treated some cases of liver injuries with fibrin foam and saw several others that were treated in the same way. It not only controlled the hemorrhage very effectively, but we felt that it also sealed off the bile ductules as the bile drainage in these cases was considerably less than what we experienced before fibrin foam was available. There is no question but that this was the best method we had for handling war wounds of the liver.

Dr. William Peyton: There is a substance called gelatin sponge being made as a substitute for fibrin foam and bovine thrombin is suggested as a substitute for human thrombin. I do not know how satisfactory these will be.

Ernest R. Anderson, M.D.
Recorder

OFFICE OF THE SURGEON GENERAL REPRESENTED AT GORGAS INSTITUTE MEETING

Major General Norman T. Kirk, Surgeon General of the Army, and Brigadier General James S. Simmons, Chief of Preventive Medicine Service, Office of The Surgeon General, both board members of the Gorgas Memorial Institute of Tropical and Preventive Medicine, recently participated in an election of three new directors to the Institute.

The three included: Spruille Braden, former ambassador to Argentina and now Assistant Secretary of State, Rear Admiral H. W. Smith, Chief of the Navy Research Division of the Bureau of Medicine and Surgery, and Colonel R. G. Prentiss, Jr., Chairman of the Army Medical Research and Development Board.

GENERAL SIMMONS GUEST OF HONOR AT DINNER

Brigadier General James S. Simmons, Chief of Preventive Medicine Service, Office of The Surgeon General, was the guest of honor at a dinner recently given by Colonel Richard P. Strong, Director of Tropical Medicine of the Army Medical School. The guests included some of the nation's leading scientists and military doctors.

In Memoriam

EARL MELVIN ANDERSON

Dr. Earl M. Anderson, Minneapolis, a Lieutenant in the Navy, died at the Naval Air Station in Glenview, Illinois, July 5, 1945, as a result of numerous injuries received in an airplane crash. He was twenty-eight years old.

Dr. Anderson graduated from the University of Minnesota Medical School in 1941 and interned at the Minneapolis General Hospital. He served a fellowship in surgery at the Mayo Foundation at Rochester, and was commissioned a Lieutenant (jg) in the medical corps of the U. S. Naval Reserve on March 3, 1942.

EDWARD THOMAS ANDERSON

Dr. Edward T. Anderson of Excelsior, Minnesota, passed away November 1, 1945, at the Veterans' Hospital in St. Cloud where he had been since 1939. He was seventy-six years old.

Dr. Anderson was born at Dubuque, Iowa, August 30, 1869. He graduated from the School of Medicine at Sioux City, Iowa, in 1895, and practiced in South Dakota before entering the service in World War I. He served three years, one of them overseas, and because of impaired health resulting from service, retired soon after his discharge and lived at Excelsior, Minnesota.

He was a member of the Excelsior Methodist Church and the Excelsior Masonic Lodge.

Dr. Anderson is survived by his wife, one daughter, Mrs. R. L. Ward of Staples, Minnesota, and one son, Dr. Arnold Anderson of Lexington, Kentucky.

FLOYD F. CLARK

Dr. Floyd F. Clark of Duluth, died suddenly November 15, 1945. He was born at Churubusco, Indiana, November 17, 1875, and obtained his medical degree at the University of Illinois in 1908. He interned at Chicago Hospital and began practice in Duluth thirty-six years ago.

Dr. Clark served as examiner for the State Boxing Commission for four years, was physician for the jail of St. Louis County for fourteen years and at times was deputy county coroner.

He was a member of the St. Louis County Medical Society, the Minnesota State and American Medical associations, Tonic Lodge A.F. and A.M. and the Order of the Mystic Shrine.

Surviving are two sons: Lt. Floyd Clark, Jr., of the Navy and Fred Clark of Houston, Texas.

F. V. LANGENDERFER

Dr. Francis V. Langenderfer was born in Ohio, December 30, 1884. He graduated from Loyola University Medical College, Chicago, in 1907.

He was commissioned a Lieutenant in the Army Medical Corps and served three years in that capacity in the Philippine Islands.

Upon his return to the United States he started practicing medicine in Knapp, Wisconsin, where he also met and married Anna Kvool. He moved to Saint Paul in 1913, and opened an office at Rice Street and University Avenue. In 1923, he moved to new offices across the street in the New Capitol Drug Building, where he practiced medicine and surgery until he became ill in February, 1943.

He was a member of the Ramsey County Medical Society, Minnesota State Medical Association and American Medical Association, and was on the staff of St. Joseph's and Bethesda Hospitals.

Dr. Langenderfer died November 26 at St. Joseph's Hospital where he had been since October 7, 1944.

VICTOR N. PETERSON

Dr. V. N. Peterson died at Bethesda Hospital, Saint Paul, on November 28, 1945, after an illness of several months. Funeral services were held in Saint Paul on December 3. Interment was at Cokato, Minnesota. He is survived by his mother, Mrs. Anna Peterson of Mankato, Minnesota, and one brother, Mr. Leonard C. Peterson of Miami, Florida.

Dr. Peterson was well known in Saint Paul, having practiced there for thirty-eight years. He was located at 885 Rice Street for 11 years and in the Lowry Medical Arts Building since 1918.

He was born in Cokato, Minnesota, on September 5, 1879, and was the eldest son of Andrew P. Peterson and Anna Peterson. He attended the Cokato High School and in 1902 received his B.A. degree from Gustavus Adolphus College at St. Peter, Minnesota. In 1906, he was graduated from the University of Minnesota with the degree of doctor of medicine. After graduation, he practiced for one year at Starbuck, Minnesota, before coming to Saint Paul.

For a number of years he was on the staffs of Bethesda and Miller Hospitals. He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. In 1925 he was admitted as a Fellow of the American College of Surgeons. He was also a member of the Saint Paul Surgical Society and served as its president in 1939.

Dr. Peterson was a Shriner and an active member of the Osman Temple Shrine of Saint Paul. He was a member of the Saint Paul Athletic Club, where he made his residence after the death of his wife.

He will long be remembered by his many friends for his cheerful nature, his kindness and his sincerity. He was greatly esteemed by his associates for his excellent judgment and professional skill. He was always willing to be of help to the younger men, and his influence will ever be felt by those whom he so generously assisted.

At this time the members of the Ramsey County Medical Society wish to express their sorrow at his passing and their appreciation of having had the opportunity to be associated with one of such high character and outstanding ability.

J. Lawrence Noble, M.D.

Effective
Convenient
Economical

THE effectiveness of Mercurochrome has been demonstrated by more than twenty years of extensive clinical use. For professional convenience Mercurochrome is supplied in four forms—Aqueous Solution in Applicator Bottles for the treatment of minor wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

Mercurochrome

(H. W. & D. brand of merbromin, dibromoxymercurifluorescein-sodium)

is economical because stock solutions may be dispensed quickly and at low cost. Stock solutions keep indefinitely.

Mercurochrome is antiseptic and relatively non-irritating and non-toxic in wounds.

Complete literature will be furnished on request.

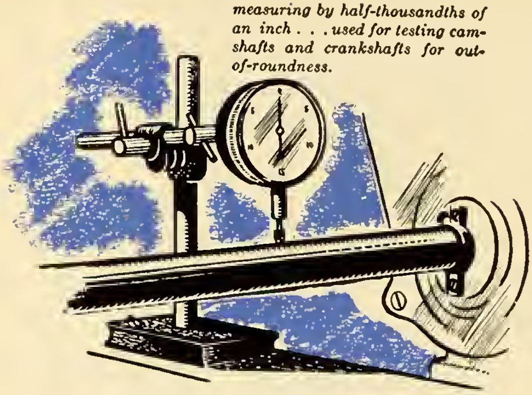
DIAL TEST INDICATOR measuring by half-thousandths of an inch . . . used for testing camshafts and crankshafts for out-of-roundness.



WHEN IT'S *Precision* YOU REQUIRE . . .

FOR the treatment of pernicious anemia, medical science has found a specific in liver therapy.

But like the highly sensitive dial test indicator which measures within .0005 inch, liver extract—to give precise results—must be manufactured with the utmost care.

. . . *And nothing less than precision will meet the requirements of the competent physician.*

For these requirements, Purified Solution of Liver, Smith-Dorsey, deserves your confidence.

Its uniform purity and potency are traceable to the conditions under which it is produced—to the capably staffed laboratories, the modern facilities, the rigidly standardized testing procedure.

You may be assured of *precision* in liver therapy when you use

PURIFIED SOLUTION OF *Liver*

SMITH-DORSEY

Supplied in the following dosage forms: 1 cc. ampoules and 10 cc. and 30 cc. ampoule vials, each containing 10 U.S.P. Injectable Units per cc.

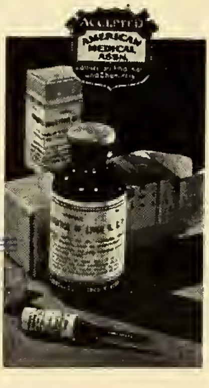
Lincoln, Nebraska
Manufacturers of Pharmaceuticals to the Medical Profession Since 1908



COMMUNICATION

Minnesota Medicine
Dear Sirs:

Some of my medical society friends might like to know what has happened to me.

I volunteered for the Army while I was at Pine City and was ordered to active duty on 26 Jan. 1943. Was sent to Carlisle Medical Field Service School and thence to Stark General Hospital at Charleston, S. C., where I was placed in the medical pool. While there I was a ward officer on medicine and also medical officer on several hospital trains evacuating patients from Stark. On 1 May, 1944, I was ordered to the 141st General Hospital which was then being trained at Kennedy General in Memphis. We worked at Kennedy while there and finally were alerted and debarked from Port of New York on 15 June 1944.

While overseas, we operated the 141st General in Wiltshire in Devizes, a small town about 35 miles East of Bristol. We had patients within two weeks after arriving so were lucky in not having to wait about. My duties were officer on medicine and I had charge of the Prisoner of War wards. I averaged about seventy active prisoner patients and had a very interesting experience. It certainly was varied from battle casualties to Weil's disease. Had a small series of peculiar types of edema with no evidence of protein deficiency or renal disease. These were the "war nephritis" cases described by German medical officers. Recovery was usually prompt but occasionally very prolonged though the patients were not very ill. I feel these were on a nutritional basis in spite of the fairly normal serum protein levels. We also had a large series of diphtheria in these prisoners. These were interesting for adult diphtheria at home was rare. All recovered. This experience was most interesting and valuable because of the great variety of conditions seen.

In December I was appointed chief of the Gastro-Enterology Section and had all the consultations in this field as well as proctoscopic examinations. This likewise was valuable training for there was ample work in a hospital of this size (we averaged 2000 beds). Duodenal ulcer and hepatitis were the most common organic states but functional disorders were by far the most common and a difficult problem in many cases to handle. One month of my overseas stay was spent in London where I worked at the main dispensary at U.K. base in the medical section. This was varied too but less interesting to me than ward work where you could follow the patient through his illness. Being in London was kept interesting, however, by the Germans and their V1 and V2 bombs. One narrow escape was enough for me.

When the war ended we were slated for Pacific duty because we had only been overseas 11 months at the time of V-E Day. Thus we were shipped out of England

(Continued from Page 76)

early in order to get back to the States for training. Our trip home in June was marvelous, 4½ days on the Queen Elizabeth, as compared to 11 days going over in slow convoy. We had our 30-day leave which I spent with my family in Rochester, then joined the 141st at Camp Crowder, Mo. From then on it was a matter of sweating it out. The war was soon over, yet we were still slated for Pacific duty and were most unhappy about it, feeling that we had done our share of work overseas. We completed our 6 weeks of training including setting up field hospitals under canvas, tropical disease control and even familiarization with hand grenades, rifle, and pistol. Finally, however, I was ordered to the 6th Service Command and left the 141st with which I had served so long.

My present job is Chief of the Gastro-Enterology Section here at Vaughan Hospital, at Hines, Illinois, where 6th Service sent me. It is a fine service with 102 active beds and is really busy. Work is varied but consists mostly of duodenal ulcer and hepatitis plus all the varieties of colitis. I find it most interesting especially as I do the proctoscopies for the hospital and see a great number of interesting conditions. I am fortunate in having an able Captain as an assistant so we can handle the work adequately. I feel I am fortunate in getting this service for I am doing the work I like, am plenty busy, and seeing much interesting medicine.

I have been fortunate throughout my Army Service in that I have done clinical medicine all the time and have not lost touch with it like so many have. I hope to be discharged early in the spring and take some more postgraduate work in Internal Medicine. That concludes my story and a long one it is.

Very truly yours,
GEORGE E. BROWN, JR., Capt., MC.

BERT SHEPARD ASSIGNED TO THE OFFICE OF THE SURGEON GENERAL

First Lieutenant Bert Shepard, who attracted nationwide attention last summer when he resumed his professional baseball career as pitcher for the Washington Senators three days after receiving his GI artificial leg from Walter Reed General Hospital, has re-entered the service at the request of The Surgeon General to aid in a program designed to help amputees get the greatest use from their prostheses.

In May, 1944, Lieutenant Shepard's P-38 was shot down over Germany. He suffered the loss of the lower part of his right leg, the operation being performed by German surgeons. After eight months in German hospitals and prison camps, he returned to the United States aboard the Gripsholm in February of this year.

Wearing a crude artificial leg fashioned from Red Cross materials by a fellow Canadian prisoner, Lieutenant Shepard was sent to Walter Reed General Hospital where he received a GI prosthesis. Within three days after his fitting, he was working out with the Washington Senators and later signed with them. He plays football and has been clocked in the 100-yard dash at 12.05 seconds. He is the wearer of the Distinguished Flying Cross, Air Medal with three clusters and the Purple Heart.—*News Notes,* No. 34, Office of Surgeon General.

Uniform Satisfaction

Schieffelin
BENZESTROL
(2, 4-di (p-hydroxyphenyl)-3-ethyl hexane)

Clinicians agree that Schieffelin BENZESTROL is a significant contribution to therapy in that it is both estrogenically effective and singularly well tolerated, whether administered orally or parenterally.

"In our hands it has proved to be an effective estrogen when administered either orally or parenterally and much less toxic than diethylstilbestrol at the therapeutic levels" (Talisman, M. R.—Am. Jour. Obstet. & Gynec. 46, 534, 1943)

"During the last two years I have used the new synthetic estrogen Benzestrol in patients in whom estrogenic therapy was indicated. The results have been uniformly satisfactory". (Jaeger, A. S. Journal Indiana State Med. Assn. 37, 117, 1944)

Schieffelin BENZESTROL is indicated in all conditions for which estrogen therapy is ordinarily recommended and is available in tablets of 0.5, 1.0, 2.0 and 5.0 mg.; in solution in 10 cc. vials, 5 mg. per cc.; and vaginal tablets of 0.5 mg. strength.

AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians will resume its annual meetings in 1946 and has now definitely chosen Philadelphia as the place of meeting, May 13-17, inclusive. Headquarters will be at the Philadelphia Municipal Auditorium, 34th Street below Spruce.

The meeting will be conducted under the presidency of Dr. Ernest E. Irons, Chicago, Illinois, and the general chairmanship of Dr. George Morris Piersol, 3400 Spruce Street, Philadelphia, Pennsylvania.

CHICAGO MEDICAL SOCIETY

The tremendous success of the First Clinical Conference held two years ago served as a mandate to the Chicago Medical Society for the annual continuation of this type of program. Last year the Conference was called off because of government restrictions on travel. This year the Society has been able to go ahead with its plans and the Conference will be held at the Palmer House, Chicago, Illinois, on March 5, 6, 7, and 8, 1946.

There will be scientific programs consisting of half-hour lectures beginning at 8:30 A.M. and continuing until 5:00 P.M. with intermissions for viewing the scientific and technical exhibits which promise to be most outstanding.

Speakers have been secured from all sections of the United States and the program committee promises a discussion of the important fields of medicine.

A banquet is being planned for Thursday night when a speaker of international reputation will talk on a topic of general interest.

Reservations for rooms should be made through The Chicago Convention Bureau, 33 North LaSalle Street, Chicago 2, Illinois. It is important that those planning to attend this Conference make their reservations as soon as possible and arrange to room with a friend. Hotel rooms are at a premium. Early planning and reservation will prevent disappointment.

MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

The first meeting for the 1945-1946 season of the Minnesota Academy of Ophthalmology and Otolaryngology was held at the Minneapolis Club on Friday, November 9, 1945.

The following men took office: Dr. K. C. Wold, Saint Paul, president; Dr. Theodore R. Fritsche, New Ulm, first vice president; Dr. C. L. Oppegaard, Crookston, second vice president; Dr. William A. Kennedy, Saint Paul, secretary-treasurer; Dr. Malcolm C. Pfunder, Minneapolis, chairman of Council.

The retiring president is Dr. A. G. Athens of Duluth.

Two papers were presented: "Air Restoration of the Anterior Chamber" by Dr. Frank Burch of Saint Paul, and "Facial Nerve Injury in Relation to Skull Fracture" by Dr. Jerome Hilger of Saint Paul.

RAMSEY COUNTY MEDICAL SOCIETY

Results of the Ramsey County Medical Association election of officers, conducted by mail, were announced at the annual meeting held on November 27 at Ancker Hospital, St. Paul. Dr. Harry B. Zimmermann succeeds Dr. Justus O'Hage as president; Dr. John M. Culligan is president-elect for 1947; Dr. John R. Aurelius is vice president, and Dr. Clayton K. Williams is secretary-treasurer.

ST. LOUIS COUNTY MEDICAL SOCIETY

The annual dinner meeting of the St. Louis County Medical Society was held on December 12 at the Northland Country Club, and election of the following officers was announced: President, Dr. P. G. Boman, Duluth, who succeeds Dr. William J. Ryan, also of Duluth; vice president, Dr. Francis W. Backnik, Hibbing; secretary-treasurer, Dr. Elizabeth C. Bagley, Duluth, succeeding Dr. Robert P. Buckley, Duluth.

The guest speaker was Walter T. Ridder, foreign correspondent for the Duluth *Herald and News-Tribune*, who presented a graphic picture of the "destitution and pauperism of the European peoples."

More than 160 physicians and their wives were present.

WOMAN'S AUXILIARY

Mrs. Edward V. Goltz, *President*
Saint Paul, Minnesota
Mrs. John K. Butler, *Editor*
Carlton, Minnesota

STATE BOARD

Mrs. E. V. Goltz presided at the November meeting of the State Board at the Minnesota Club in Saint Paul. A large group of members was present and gave interesting reports of their organizations. The group was urged by Mrs. Harlow J. Hanson to encourage nurses to enter training. Although candidates are no longer accepted for Cadet Nurses, she reminded the group that the hospitals have their own courses and are happy to have applicants.

At the luncheon Dr. Wallace P. Ritchie talked on his experiences with the 26th General Hospital. Dr. Ritchie's mother, Mrs. Harry P. Ritchie, who has long been active in the Ramsey County Auxiliary and is a former state president, was also present.

* * *

BLUE EARTH COUNTY

The Blue Earth County Auxiliary met at the Mankato Clinic to elect officers and make plans for the year. Mrs. George Penn was elected president; Mrs. E. A. Sohmer, vice president; Mrs. Roger Hassett, secretary, and Mrs. P. G. Hoeper, treasurer. Committee chairmen appointed were *Hygeia*—Mrs. W. B. Kaufman; *Legislation*, Mrs. Roy Andrews; *Health Education and Public Relation*, Mrs. M. I. Howard, Mrs. O. H. Jones and Mrs. P. G. Hoeper; *Cancer Control*, Mrs. A. F. Kemp, Mrs. W. B. Kaufman, Mrs. M. I. Howard and Mrs. P. G. Hoeper. The doctors joined the ladies for a social evening after the meeting.

* * *

GOODHUE COUNTY

Mrs. R. F. Hedin was hostess at the November meeting of the Goodhue County Auxiliary. Because of the small membership it was decided to meet less frequently. However, members are keeping up their good work in making dressings for the Cancer Home in Saint Paul.

* * *

HENNEPIN COUNTY

Mrs. Erling Platou and Mrs. James Johnson were hostesses at the November meeting in the Medical Arts Building Lounge. Two members of the Auxiliary gave a musical program—Mrs. Richard Giere accompanied Mrs. A. S. Hoiland, who sang a vocal solo. Mr. Francis Harjashi, Professor of Japanese at the University of Minnesota, talked on "Out and Moved."

Auxiliary members staffed a booth at Dayton's at which they sold articles made by the Glen Lake Sanatorium patients, November 8 and 9. They netted over $3,000 from the sales.

KANDIYOHI-SWIFT-MEEKER COUNTIES

Mrs. S. B. Lindley entertained the Auxiliary at the Willmar State Hospital in November. Members heard an interesting talk on "Tuberculosis in the Army" at a joint meeting of the Medical Society and the Auxiliary. Afterwards both groups played bridge.

* * *

MOWER COUNTY

Members of the Mower County Auxiliary met at the home of Mrs. B. K. Cromwell and made cancer dressings.

* * *

OLMSTED-HOUSTON-FILLMORE-DODGE COUNTIES

Mayo Foundation House was the meeting place of the Auxiliary last month. Members heard Evelyn Beyer, director of pre-school activities of the child health project, talk on nursery schools.

* * *

PARK REGION

Nineteen members of the Northern Minnesota Auxiliary were guests of the Park Region Auxiliary at Fergus Falls, November 3, when the Park Region Auxiliary observed the twenty-fifth anniversary of its organization at Fergus Falls in 1920. Luncheon was served at River Inn Hotel. Later, Mrs. A. C. Baker entertained at tea. Mrs. J. L. Morrill and Mrs. E. V. Goltz were guests of honor. Mrs. Goltz urged the members to become more active in civic and medical organizations.

One hundred twenty-five members and guests attended the banquet at the State Hospital in the evening. The hospital orchestra furnished dinner music. Dr. W. A. O'Brien, toastmaster, introduced Dr. Richard Bardon, president of the St. Louis County Medical Society, and Dr. J. L. Morrill, president of the University of Minnesota, as speakers of the evening.

* * *

ST. LOUIS COUNTY

New members of the Auxiliary and wives of the interns from St. Mary's and St. Luke's Hospitals were guests at a luncheon at the Hostess House. After a short business meeting, the women played bingo, using as prizes white elephants donated by the members. The proceeds, $14.85, will be added to the philanthropic fund. This amount combined with the proceeds for the rummage sale netted over $200 this year.

* * *

STEARNS-BENTON COUNTIES

Mrs. Wm. Friesleben of Sioux Rapids entertained her group at a pot luck supper in November. Mrs. T. N. Fleming, public relations chairman, reported on the progress of the tuberculosis contest, for which the Auxiliary gives a $5.00 prize.

* * *

WASHINGTON COUNTY

Eight members and two guests met at the home of Mrs. D. Kalinoff in Stillwater for the November meeting of the Washington County Auxiliary.

◆ Of General Interest ◆

* * *

Dr. H. Robert Ransom, formerly of Staples, has opened offices for practice in Crosby and Ironton, since his recent discharge from the Army Medical Corps. He will make his home in Crosby.

* * *

Dr. A. J. Hagen of Moorhead was a delegate to the U. S. Chapter of the International College of Surgeons which convened in Washington, D. C., December 6, 7 and 8, 1945.

* * *

Dr. W. W. Will, a former president of the Minnesota State Medical Association, was elected a Fellow of the International College of Surgeons at the annual convocation at Washington, D. C., December 7, 1945.

* * *

Dr. William R. Blomberg has purchased the building which he has been occupying in Princeton and will begin extensive remodeling as soon as the weather permits.

* * *

Captain Gilbert P. Wenzel, Saint Paul, who has been stationed in the Central Pacific for the past eight months, was recently transferred from Guam to Okinawa.

* * *

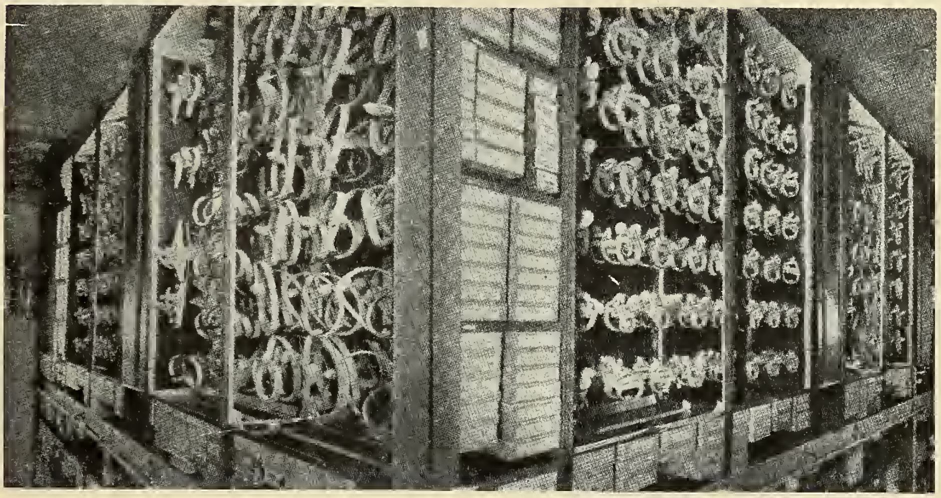
Major Louis Sperling, Minneapolis, has located in Beverly Hills, California. He is associated with Mark Rabwin in the practice of surgery at 9730 Wilshire Boulevard.

* * *

Major Harold J. Black has returned to Saint Paul following his discharge from service. He was Commanding Officer of the 53rd Field Hospital in the active service in Normandy, Belgium and Germany.

(Continued on Page 86)

A COMPLETE TRUSS AND APPLIANCE DEPARTMENT AT YOUR SERVICE



Obviously, no doctor can keep on hand all of the sizes and the variety of styles of trusses, supports, and hosiery his patients are likely to need. The investment and space required would be all out of proportion to the demand.

To provide you with a practical solution to this problem, we maintain the largest and most complete truss and supporter department in the Northwest. We carry in stock thousands of trusses and supports. We also maintain a complete fitting department under the direction of experienced men who are competent to handle the most difficult cases. In other words, we carry the stock and provide the facilities that enable you to give your patients the finest truss service available.

All of the facilities of this department and every other department in our organization are yours to use any time you wish. Innumerable physicians realize the advantages of sending their orders to us for such appliances. They know they can obtain any type of truss, physiological support or elastic stocking from us and that they will always receive the very best in quality. Our vast stocks insure prompt service. You can send your patients to us with the assurance that they will be given every consideration. If you wish to fit your patients in your own office, the trusses and supports required may be ordered by mail with perfect confidence. Orders are shipped the same day they are received.

If you are not already making use of our truss service, we urge you to do so and see for yourself, as thousands of others are doing, that here is the place to get quality merchandise and prompt, efficient service at economical prices.

MINNEAPOLIS MINNESOTA

(Continued from Page 84)

Dr. Harold Hans Noran, formerly of Washington, has opened offices at 507 Physicians and Surgeons Building, Minneapolis. He will limit his practice to Neurology and Psychiatry.

* * *

Dr. Maurice L. Straus, who has returned from service, will reopen his office at 726 White Bear Avenue, Saint Paul, on February 1. Dr. Straus served as captain in the Medical Corps with the 41st Infantry in northern Australia and in New Guinea.

* * *

Dr. Willis L. Herbert, captain in Army Medical Corps, entered service in March, 1944. He served in blood donor centers in Detroit and Minneapolis, and the separation center at Camp McCoy. He has resumed general practice with offices at 307 Hennepin Avenue.

* * *

Dr. Victor K. Funk, commander, entered service in April, 1942, and served as senior medical officer aboard the *USS Orion* in the Pacific for seventeen months. Dr. Funk has rejoined the staff at Glen Lake Sanatorium.

* * *

Dr. Henry W. Woltman was elected staff president and Dr. John Berkman was re-elected secretary of the Mayo Clinic staff at the annual meeting held at the Foundation House. Dr. John de Jarnette Pemberton is the retiring president.

* * *

The marriage of Dr. James Peter Murphy to Lieutenant Barbara E. Fuller, Army nurse, took place at the post chapel at Langley Field, Hampton, Virginia. Dr. Murphy is the son of Dr. and Mrs. Francis E. Murphy, of Minneapolis.

* * *

Dr. George Olds, who was associated with Dr. Bernard Gallagher in the practice of medicine at Waseca at the time of his induction into military service, has opened offices in New Richland. Dr. Olds served as a captain in the Army Medical Corps.

* * *

Dr. Rolf M. Iverson, formerly of Pasadena, has become associated with Dr. Robert G. Allison in the practice of radiology. He served a Fellowship in the Graduate School of the University of Minnesota at Rochester before coming to Minneapolis.

* * *

At a meeting of the Range Medical Society held in Virginia, Minnesota, on December 18, 1945, the following officers were elected for the year, 1946: President, Dr. R. A. Salter, Virginia; Vice President, Dr. F. R. Kotchevar, Eveleth; Secretary, Dr. David A. Sher, Virginia.

* * *

Dr. Nathan C. Plimpton, Jr., has been discharged from the Medical Corps of the Army and is associated with Dr. O. J. Campbell, 1251 Medical Arts Building, Minneapolis, in the practice of surgery. Dr. Plimpton was a Fellow in the Graduate School of the University of Minnesota at Rochester before enlistment.

* * *

While on a hunting trip near Cayuga, North Dakota, Dr. Frederick A. Thysell, of Moorhead, slipped as he got out of his car and fractured a vertebra. Dr. Thysell was taken by ambulance to St. Angar's Hospital in Fargo, where he was expected to have to remain for some weeks.

* * *

Dr. Einer M. Monson, captain in the Army, entered the service in November, 1942, and was on Surgical Service with the 327th Station Hospital in England and France for sixteen months. He has returned to general practice with offices at 4144 Fremont Avenue North.

* * *

Dr. Karl Sandt, major, entered service in February, 1942, and went overseas in October, 1942. He was Chief of Eye Service for General Hospital 26 in England North Africa and Italy. He has returned to his practice of ophthalmology in his offices in the Medical Arts Building.

* * *

Dr. Walter Alvarez, Mayo Clinic, was guest lecturer for the Autumn Postgraduate Course of Queen's University Medical Faculty in Kingston, Ontario. Dr. Alvarez' subjects were "Diagnostic Hints for General Practitioners", and the "Diagnosis of Puzzling Types of Pain."

* * *

Dr. William J. Noonan, lieutenant colonel, entered service in May, 1941, and served as Chief of the Urology Department at Camp Gruber, Oklahoma, and Glennan General Hospital, Okmulgee, Oklahoma. He has resumed his practice of urology in temporary offices in the Medical Arts Building.

* * *

Dr. Paul W. Kebler, major, entered service in April, 1942, and was sent as Laboratory Officer for General Hospital 26 in England, North Africa, and Italy. He has returned to his position as Chief of Laboratories of the Division of Preventable Diseases at the University of Minnesota.

* * *

Dr. Robert E. Johnson, major, entered service in February, 1942, and went overseas in October as war surgeon with General Hospital 26 in North Africa and Italy. Later he was commanding officer of the Adriatic Base Command General Hospital. He has returned to general practice, with offices in the Medical Arts Building.

* * *

The War Department has announced the promotion of Dr. Edward Dyer Anderson, of Minneapolis, to the rank of captain in the Navy Medical Corps.

Captain Anderson is now serving as Chief Medical Officer at the Marine Base on Parris Island, North Carolina, after twenty-one months of duty aboard a hospital ship.

* * *

After three years in the armed forces, Dr. Russel Carlson has returned to his practice in association with Dr. Francis M. McCarten in Stillwater. Dr. Carlson had been with Dr. McCarten for a year and a half when he was inducted into military service, where he was a captain with twenty-one months' duty in the European Theatre.

Dr. Dean K. Rizer, major, entered service in November, 1942. He went overseas in July, 1944, and served as Chief of the Medical Section of the 119th General Hospital in England, and the 220th General Hospital in France. He has returned to his practice of internal medicine with offices in the Medical Arts Building.

* * *

After three years as commander in the Navy, Dr. Chester J. Olson has returned to his offices at Belle Plaine. Dr. Olson's service included duty at Camp Farragut, Idaho, Columbia University, Okinawa, and the Naval Training Base at Great Lakes, where for the past four months he has been engaged in discharge examinations.

* * *

Dr. John R. Paine, lieutenant colonel, entered service in February, 1942, and went overseas in October of the same year. He was Assistant Chief of Surgical Service with General Hospital 26 in England, North Africa and Italy. Dr. Paine has returned to his position of Associate Professor in Surgery at the University of Minnesota.

* * *

Dr. Reinhold M. Ericson, major, in service from July, 1943, was sent overseas in November, 1944, and attached to the 116th Evacuation Hospital at Sarreburg, France, and later, after the Rhine crossing, near Munich and at the Dachau concentration camp. An eye, ear, nose and throat specialist, his offices are in the Physicians and Surgeons Building.

* * *

Dr. Rudolph E. Hultkrans, captain, in Army, entered service in August, 1943; was twenty-two months as chief of orthopedics at the 103rd Evacuation Hospital from the Normandy landing and through France into Germany. Was later assigned to the 48th General Hospital in Marseilles, France. Has returned to his offices in the Medical Arts Building for the practice of surgery.

* * *

Dr. Lester Fogner, who was practicing in association with Dr. Wallace R. Smith at Grand Marais prior to his induction into the armed forces, has been appointed on the staff of the Veterans' Hospital in Minneapolis.

While he was in service Dr. Fogner, a major in the 28th Infantry, was taken prisoner by the Germans on December 17, 1944. He was liberated the following May.

* * *

Dr. Warner Ogden has resumed practice at his former office, 714 Lowry Medical Arts Building, Saint Paul, following his discharge from the Navy. Stationed first at the Naval Hospital on Treasure Island, San Francisco, Commander Ogden spent twenty-one months at a Shore Base in the Northern Solomons with Naval Aviation, and since June, 1945, has been assigned to the Naval Hospital at Corvallis, Oregon.

* * *

At the annual clinical meeting of the Ramsey County Medical Society held at Ancker Hospital, November 29, 1945, the staff voted to name the annual meeting the Arnold Schwyzer Clinical Meeting of the Ramsey County Medical Society in memory of the late Dr. Schwyzer,

who for many years was one of the outstanding Clinicians of Saint Paul and the originator of the annual clinical meeting of the society.

* * *

Dr. Donald McCarthy, captain in the Navy, entered service in September, 1940. He was in Naval Medical Corps recruitment work for fifteen months and was then made Chief of Medicine on the H.S. *Relief,* with duty in both Atlantic and Pacific Theatres for the following two years. Subsequently he was Chief of Medicine at the Naval Hospital at Great Lakes, Illinois, and then Senior Medical Officer on Midway Island. He has resumed his practice of internal medicine with offices in the Medical Arts Building.

* * *

Dr. William T. Walsh, captain, entered service in February, 1942, and went overseas in October, 1943, as flight surgeon for the 312th Bombardment Group. He wears six battle stars, a Unit Citation and the Philippine Liberation Ribbon and Star, earned in service in Australia, New Guinea, the Philippines and Okinawa. He has returned to general practice with offices in the La Salle Building.

* * *

Dr. Oscar Lipschultz, lieutenant colonel, entered service in March, 1942, and went to North Africa and Italy in October of the same year as Chief of X-ray Service for General Hospital 26. Later he was assigned to the 45th General Hospital in Italy. Dr. Lipschultz has resumed his practice in his offices in the Medical Arts Building and has also returned to his position as Director of X-ray Department of the General Hospital.

* * *

Dr. Paul Swedenburg, formerly of Swanville, has entered medical practice at Little Falls, where he will share offices with Dr. Douglas L. Johnson and Dr. Roman V. Fait.

A graduate of the University of Minnesota Medical School, 1931, Dr. Swedenburg was associated with Dr. Edwin J. Simons in Swanville when he was inducted into service five years ago.

* * *

Dr. W. McK. Craig, formerly neuro-surgeon of the Mayo Clinic who is at present chief of the Bethesda Naval Hospital, Maryland, was one of four distinguished surgeons elected to honorary fellowship in the International College of Surgeons at Washington, D.C., on December 6. Dr. Craig is the only physician in American history ever to be given the rank of Rear Admiral He was the principal speaker at the annual banquet, his subject being "Surgery in the Navy."

* * *

Dr. R. B. Graves, while in Red Wing on terminal leave, purchased a building where he expects to occupy offices some time in January. Before entering military service in 1942, Dr. Graves was a member of the Medical Block Clinic in Red Wing.

In seventeen months of overseas duty as Flight Surgeon of a heavy bomber squadron, Dr. Graves earned the ETO ribbon with six battle stars and flight surgeon's wings.

* * *

Dr. W. S. Broker, who has been in tuberculosis sanatorium work for the past twenty-four years, has resigned his position as superintendent of Fair Oaks Lodge Sanatorium at Wadena to accept an appointment as superintendent of Pleasant View Sanatorium, East St. Louis, Illinois. He succeeds Dr. Robinson Bosworth, who was formerly executive secretary of the Minnesota Sanatorium Commission. Dr. Bosworth intends to enter private practice in Rockford, Illinois.

* * *

Dr. I. E. Bigler, a 1938 graduate of the University of Minnesota School of Medicine, who has been in military service since 1941, has opened offices in Crosby and bought a home there. Prior to his induction into the armed forces, he had been practicing at Ada, Oklahoma, for two years. Dr. Bigler was a flight surgeon with the Air Transport Command in the European Theater of Operations and also served with an Arctic Search and Rescue Squadron in Labrador for a year.

* * *

After two years in the Pacific Theatre, Dr. John E. Westrup has been discharged from service and is again in practice in Lanesboro, where he had been located for three years prior to his induction into the Navy. As lieutenant commander, Dr. Westrup served at Saipan, Attu and Tarawa. Later he was assigned to the Office of Procurement in Chicago, and recently he was at the Separation Center at Great Lakes Naval Station.

* * *

The lectures given at the December session of the Annual Industrial Safety School in Duluth included the following: "Digestive Disturbances," by Dr. Philip F. Eckman; "Industrial Dermatoses," by Dr. Merriam G. Fredericks; "Respiratory Hazards in Industry," by Dr. G. Arvid Hedberg; "Heart Disease," by Dr. Frank J. Hirschboeck; "Sprains and Strains," by Dr. S. Sverre Houkom; and "Sickness Can Be Prevented," by Mario Fischer, city director of public health.

* * *

Dr. Andrew V. Grinley, formerly of Rockwell City, Iowa, is now associated in practice with Drs. Francis and Raymond Jolin and Maurice McKenna at Grand Rapids.

Dr. Grinley graduated from Rush Medical College in Chicago and interned at Ancker Hospital in Saint Paul, where he was also resident physician. He was in military service from May, 1942, until his recent discharge, and served in the ETO for thirty-nine months.

* * *

Mr. M. Albert Linton, chairman of the Life Insurance Medical Fund, has announced that grants totaling $126,000 to be used this year for research into the cause of cardiovascular disease have been made to Columbia, Yale, Washington (St. Louis), Minnesota and Pennsylvania Universities, and to Southwestern Medical College at Dallas, Texas. Dr. Maurice Visscher of the Department of Physiology and Dr. Arthur Kirschbaum of the Department of Anatomy will supervise the expenditure of research funds at the University of Minnesota.

* * *

Dr. Harry B. Neel returned to his practice of surgery in the Albert Lea Medical and Surgical Center in November, after three years service in the Navy. In addition to duty at several naval hospitals in the United

States and Hawaii, Dr. Neel served aboard the H. S. *Solace* during the campaigns of the Marshall and Palau Islands, and the Mariannas.

Since his return from overseas duty a year ago, Dr. Neel had special training in x-ray diagnosis and was in the x-ray division at the U. S. Naval Hospital in Norman, Oklahoma, until his recent discharge.

* * *

After twenty-five years of medical practice in association with his brother, Dr. Berton J. Branton, at the Willmar Clinic, Dr. Aloys F. Branton has left Willmar for Chattanooga, Tennesse, where he will be superintendent of the Baroness Erlanger Hospital, an institution of 700 beds.

Dr. Branton is a graduate of the University of Minnesota Medical School, Class of 1920. He served as president of the Minnesota Hospital Association for several terms and had been executive secretary for the past eight years.

* * *

After an absence of five years in the Army Medical Corps, Dr. N. J. Kulzer has returned to his practice of medicine and surgery in Hastings. With rank of captain, Dr. Kulzer was on overseas duty for sixteen months. In January, 1943, he was transferred to the O'Reilly General Hospital, Springfield, Missouri, orthopedic and plastic service. In April, 1945, he was sent to Carson General Hospital, Colorado Springs, for surgical service and remained there until discharged in November.

Dr. W. E. Parker, who has been associated with the Davis Clinic at Wadena, since his honorable discharge from the U. S. Army in August, 1945, has located in Sebeka.

Dr. Parker graduated from the medical department of the University of Minnesota in 1934 and served two years interneship in Oklahoma City, Oklahoma. He then practiced medicine at Davis, Oklahoma, for six years, until he entered the service in May, 1942.

* * *

Dr. Clayton E. J. Nelson, recently discharged from the Army Medical Corps after three years of service, is now practicing at the Gamble Clinic in Albert Lea.

Dr. Nelson is a graduate of the University of Minnesota Medical School, and served his internship at Bethesda Hospital, St. Paul, and Augustana Hospital, Chicago. While in service he was on the staff of the 79th General Hospital, which was located successively at Belfast, Ireland, Southhampton, England, and north of Rheims, France, where he specialized in orthopedics.

* * *

A fire, which is believed to have originated in a defective heating plant, completely destroyed the office of Dr. William G. Rogne's at Spring Grove, while the doctor was in El Paso, Texas, awaiting his discharge from military service. When the blaze was finally extinquished, all that remained of the fine structure which Dr. Rogne had completed in 1941 were the outside walls. During his absence, Dr. Rogne had stored his equipment in the building and some of it was saved. Both building and equipment were fully covered by insurance.

* * *

Dr. Marland R. Williams, Cannon Falls, has announced that hereafter he will be associated in practice with Dr. Ralph H. Larson, who was recently released from military service.

Dr. Larson graduated from the University of Minnesota Medical School in 1940 and entered the Army Medical Corps the following year. He was on duty in military hospitals in this country until 1943, when he was sent to the European Theatre as battalion surgeon with an infantry division. Wounded, he was evacuated to England and after his recovery was attached to a general hospital there.

* * *

Dr. Victor J. Bruder has resigned as radiologist at the Winona General Hospital and the Winona Clinic and hereafter will be associated with the Gunderson Clinic in La Crosse, Wisconsin.

A native of London, England, Dr. Bruder received both his Bachelor of Science and medical degrees from Loyola University in Chicago. Following the completion of his internship at the Waterbury Hospital in Waterbury, Connecticut, he specialized in x-ray diagnosis and treatment and radium therapy at Johns Hopkins Hospital in Baltimore. He was also instructor in Radiology at Johns Hopkins University. He has been certified as a specialist by the American Board of Radiology, and is a member of the National Board of Medical Examiners.

* * *

Dr. Alvin M. Nielson, recently discharged from the Navy after three years of service, has returned to his practice in Northfield.

Following a course in jungle training on Samoa, Dr. Nielson, with rank of lieutenant, served with the Second Marine Division in New Zealand and participated in the campaigns of Tarawa, Saipan and Tinian. He was awarded the Legion of Merit—one of the highest Navy decorations—a Presidential Citation, and the Purple Heart.

Dr. Nielson graduated from the University of Minnesota Medical School and served his internship at St. Joseph's Hospital in Saint Paul. He had been in practice in Northfield for two years when he was called into service.

* * *

Dr. Robert Otto Meyer, whose books and articles—numbering about 350—are standard works in medical libraries, was admitted to American citizenship in the Minneapolis Federal Court in December.

Dr. Meyer, honorary professor of gynecological pathology at the University of Berlin, fled with his wife from Germany when war was declared in 1939. He was enabled to come to America where the University of Minnesota made him a clinical associate without pay. Since then his expenses have been paid by American physicians who were his former students, with some assistance from the Jewish Refugee Fund. Dr. Meyer is now engaged in private teaching.

Dr. John McKelvey, head of the Department of Obstetrics and Gynecology at the University, is one of a number of American physicians who were privileged to study under Dr. Meyer in Berlin.

Mrs. Meyer died in this country in 1940.

* * *

Announcement has been made by Dr. Harry N. Sutherland, of Shipman Hospital at Ely, of the appointment of Major John D. Barker to the hospital staff.

Dr. Barker, a member of the Army Medical Reserve Corps, was practicing at Warren when he was called to active duty in July, 1941. As a first lieutenant, he served at a station hospital at the Portland Army Base until January, 1943, when he was ordered to the aviation school at Randolph Field, Texas, for study. On completion of his work he was returned to the West Coast where he served as flight surgeon with various groups until November, 1943, when he was sent overseas. He returned from Munich last fall wearing two Presidential Unit Citation ribbons, the Bronze Star Medal and six battle stars.

A native of Hibbing, Dr. Barker graduated from the University of Minnesota School of Medicine in 1939 and completed his internship at St. Mary's Hospital in Duluth in 1940.

* * *

Drs. Arnold O. Swenson, Karl E. Johnson, Daniel W. Wheeler and Gordon C. McRae, all of Duluth, have been discharged from military service and are again in practice.

Dr. Swenson — commander — was in service for four and a half years and stationed at Naval hospitals in Bremerton, Washington, Portsmouth, Virginia, and San Francisco. He served as Chief of Surgery in a fleet hospital in New Guinea and Senior Medical Officer at a Navy base in Manila.

Dr. Johnson — Commander — served four and a half years as Senior Medical Officer and Chief of Surgery in this country, Hawaii, Midway Islands, Kwajalein, Guam and Majuro. He wears the Purple Heart for wounds received on Guadalcanal, and for his surgical work was honored with a special letter of commendation and a Presidential Unit Citation.

Dr. MacRae — lieutenant colonel — entered service in 1942. He was Commanding Officer of the 34th Station Hospital in England for two years, and later held the same office in the 53rd General Hospital.

Dr. Wheeler — captain — enlisted in the Navy immediately after Pearl Harbor. He was stationed at a Naval Base Hospital in Bremerton, Washington, and later was Executive Officer of a Corps Evacuation Hospital on Okinawa.

* * *

The Hennepin County Medical Society has announced the return from military service of the following physicians:

Dr. Charles A. Aling, major, assigned to 100th Evacuation Hospital in France and Germany, has returned to his offices at 2300 Central Avenue, Minneapolis.

Dr. Samuel G. Balkin, major, attached to evacuation hospital throughout entire Italian campaign has returned to offices in the Medical Arts Building.

Dr. Reuben Berman, major, entered service in August, 1941, and served as flight surgeon in the Eighth Air Force in England, and was later on a medical intelligence team with the Ninth Air Force in France, Germany and Austria. He was awarded the Bronze Star Medal. Dr. Berman has resumed practice of internal medicine in temporary offices in the Medical Arts Building.

Dr. Harvey Brekke, captain in the Army, entered service in June, 1942, sent overseas in November, 1943, assigned as medical and surgery officer with the Eighth Convalescent Hospital in England, France, Holland and Germany. Dr. Brekke has returned to his offices in the LaSalle Building, where he is associated with Dr. Iver Sivertson.

Dr. Carl G. Casper, major, entered service in April, 1941, went to South Pacific in March, 1942, where he served throughout entire New Guinea campaign as orthopedist with the Tenth Evacuation Hospital and the 363rd Station Hospital. Returned to this country, he was assigned to the Mayo General Hospital in Galesburg, Illinois. He has resumed practice of orthopedics in Medical Arts Building.

Dr. Ray F. Cochran, lieutenant-commander, entered service in October, 1942, was attached to Milne Bay Hospital and participated in five landings; later at the Naval Hospital in San Diego, California. He has resumed his practice of obstetrics, with offices at 1009 Nicollet Avenue.

Dr. Reuben F. Erickson, lieutenant colonel, entered service in February, 1942, and served as executive officer of the Twenty-sixth General Hospital in North Africa and Italy. He returned to this country and was executive officer at the convalescent hospital at Camp Butner, North Carolina. He has resumed his practice of gynecology and obstetrics, with offices in the La Salle Building.

* * *

The Ramsey County Medical Society has announced the return from military service of the following members:

Dr. Walter D. Brodie, lieutenant commander, in service from May, 1945, to September 27, 1945. Offices in Lowry Medical Arts Building.

Dr. Byron B. Cochran, lieutenant colonel, in service from January 1941, to January, 1946. At Miller Hospital under a University Fellowship in Opthalmology.

Dr. Henry B. Clark, Jr., major, in service from December, 1940, to February, 1946. Offices in Lowry Medical Arts Building.

Dr. Kenneth C. Cook, captain, in service from May, 1942, to June, 1945. Office address, 896 Payne Avenue.

Dr. Robert K. Grau, captain, in service from February, 1942, to November, 1945. Offices at 366 North Prior Avenue.

Dr. Albert F. Hayes, major, in service since February, 1942; terminal leave expires on March 8, 1946. Offices in Lowry Medical Arts Building.

Dr. William W. Heck, major, in service from October, 1942, to October, 1945. Offices in Lowry Medical Arts Building.

Dr. R. W. Marks, captain, in service from November, 1941, to December, 1945. Offices at 61½ West Winifred Street.

Dr. J. Lawrence Noble, major, in service from September, 1942, to October, 1945. Offices in the Lowry Medical Arts Building.

Dr. Burton Rosenholtz, lieutenant commander, in

UNIVERSITY NEWS

An electron microscope has recently been installed in Millard Hall at the University of Minnesota Medical School. The following are among the investigations which will involve the use of the microscope: the intracellular identification of a viruslike agent responsible for the high percentage of mammary carcinoma in susceptible strains of mice; microscopic examination of bone, dentin and enamel; a study of the nature of virus inclusions in certain diseases such as vaccinia and herpes; studies of the finer details of bacteria with diameters of the order of 0.5 microns.

A gift of $25,000 was made to the Medical School by the Ebin Foundation of Minneapolis in support of five graduate medical fellowships of $1,000 a year, each to be awarded to veterans of World War II immediately.

Dr. J. Arthur Myers, Professor of Preventive Medicine and Public Health, has been elected Editor-in-Chief of the *Journal of the American College of Chest Physicians.*

Dr. Wesley W. Spink, Associate Professor of Medicine, gave the First Annual Newton Evans Lecture in Bacteriology and Pathology at the College of Medical Evangelists on November 29, 1945. His lecture was entitled "Brucellosis: Diagnostic and Therapeutic Considerations."

At the invitation of the Yale Medical Society, Dr. Robert G. Green, Professor of Bacteriology, presented a lecture on "Health and Disease in Wildlife as Exemplified by Tularemia," on January 9. During the period of his three-day visit; he also gave seminars on: "Immunology of the Milk Factor"; "Vitamin B_4 Inactivation by Raw Fish"; and "Cell-Blockade by Modified Distemper Virus."

Dr. Owen H. Wangensteen, Professor of Surgery and Head of the Department, presented a lecture on December 14 before the Alpha Omega Alpha Society at Stanford Medical School, California, entitled "Intestinal Obstructions." On December 15 he presented a lecture before the California Academy of Medicine, San Francisco, entitled "The Ulcer Problem."

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

MEN WITHOUT GUNS. Text by DeWitt Mackenzie, War Analyst of the Associated Press; descriptive captions by Major Clarence Worden, Medical Department of the United States Army; foreword by Major General Norman T. Kirk, Surgeon General, United States Army. 152 pages. Illustrated, including 118 plates in full color by famous contemporary artists. Price $5.00, cloth. Philadelphia: Blakiston Co., 1945.

CHARTER OF SUGGESTED SCHOOL POLICIES. Published by the Health Education Council, 10 Downing St., New York. Obtainable through Teachers' College, Bureau of Publications, Columbia University, New York, Price $0.25.

Devised as a guide to show how schools and communities can devise balanced programs of health education and health care in schools, this document represents the combined viewpoints of fifteen national organizations concerned with school health. It contains many valuable suggestions for those concerned with the health and nutrition of school children.

PEDIATRIC X-RAY DIAGNOSIS. John Caffey, M.D., Associate Professor of Pediatrics, Columbia University. 838 pages. Illus. Price $12.50. Chicago: Year Book Publishers, 1945.

If one were to say that this book fills a definite need, he would be correct in so doing, because it is an excellent work on diagnostic roentgenology rather than on the roentgenology of pediatrics alone, as the title states. With the exception of the roentgen diagnosis of degenerative diseases, pregnancy, gynecology, and oncology, Caffey's "Pediatrics X-Ray Diagnosis" treats most of the subjects encountered in general diagnostic roentgenology in an admirable manner.

The text is divided into various sections, such as the head and neck, the abdomen and gastro-intestinal tract, et cetera. The sections on the extremities and spine, which make up one-third of the book alone, make it worth while to anyone interested in these fields of medicine. The thoracic section constituting one-fourth of the book is invaluable to the pediatrician, cardiologist and, of course, the roentgenologist and general practitioner.

Controversial subjects of roentgenology, such as the matter of the diagnosis of appendicitis by x-ray and the thymus question, are treated with positive finality, a spirit which pervades the entire work. The limits of roentgen diagnosis are not underemphasized. The pathological terminology is unusually good.

The make-up of the book is exceptionally good, the illustrations are clear, and the diagrams informative. Typographically, it is very easy to read.

The outstanding features are two in number: (1) the rational approach to roentgenology based on embryology, anatomy and pathology, and (2) the numerous "pearls" of incidental information found in the work. The book is modern but does not seem to be dated and can be recommended to anyone who is ever in the familiar situation of deducing diagnostic information from a roentgenogram.

Leo A. Nash, M.D.

REPORTS AND ANNOUNCEMENTS

(Continued from Page 80)

WASHINGTON COUNTY SOCIETY

The annual meeting of the Washington County Medical Society was held December 11, 1945. Aside from the election of officers for 1946, an interesting discussion of health preserving activities in our schools was held.

The meeting was graced by the presence of two members just released from service, Captain George McC. Ruggles, M.D., of Forest Lake and Captain Russell E. Carlson, M.D., of Stillwater.

Major William W. Moir, M.D., is now serving a residency in the Wisconsin General Hospital at Madison, Wisconsin. That leaves only one member still in the service, Commander Samson, M.D., who is expected to be released at an early date.

W. R. Humphrey, M.D., who is vacationing in his native state, Virginia, took time to attend the meeting of the International College of Surgeons in Washington. He is expected home sometime soon.

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

SHOULD VITAMIN D BE GIVEN ONLY TO INFANTS?

VITAMIN D has been so successful in preventing rickets during infancy that there has been little emphasis on continuing its use after the second year.

But now a careful histologic study has been made which reveals a startlingly high incidence of rickets in children 2 to 14 years old. Follis, Jackson, Eliot, and Park* report that postmortem examination of 230 children of this age group showed the total prevalence of rickets to be 46.5%.

Rachitic changes were present as late as the fourteenth year, and the incidence was higher among children dying from acute disease than in those dying of chronic disease.

The authors conclude, "We doubt if slight degrees of rickets, such as we found in many of our children, interfere with health and development, but our studies as a whole afford reason to prolong administration of vitamin D to the age limit of our study, the fourteenth year, and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."

*R. H. Follis, D. Jackson, M. M. Eliot, and E. A. Park: Prevalence of rickets in children between two and fourteen years of age, Am. J. Dis. Child. 66:1-11, July 1943.

MEAD'S Oleum Percomorphum With Other Fish-Liver Oils and Viosterol is a potent source of vitamins A and D, which is well taken by older children because it can be given in small dosage or capsule form. This ease of administration favors continued year-round use, including periods of illness.

MEAD'S Oleum Percomorphum furnishes 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10- and 50-c.c. bottles and bottles of 50 and 250 capsules. Ethically marketed.

MEAD JOHNSON & COMPANY, Evansville 21, Ind., U.S.A.

nd MAPHARSEN

nited States Navy records[1] consistently show the relatively low toxicity f MAPHARSEN. Over the ten-year period, 1935-1944 inclusive, Navy eports indicate one fatality for every 167,826 injections of MAPHARSEN. ompare this to the Navy reports on neoarsphenamine for the same eriod which show one fatality in every 28,463 injections.

APHARSEN (meta-amino-para-hydroxyphenyl arsine oxide (arsenoxide) ydrochloride) offers another great advantage in that its solution does ot become more toxic on standing, nor does agitation or exposure to ir increase its toxicity. Stokes[2] states that no loss of efficacy or increase toxicity result when the solution is allowed to stand for several hours xposed to the air. Therefore, haste need not be made in preparation f the solution for injection.

NEW METHOD
# of Penicillin Inhalation Therapy

Indicated for Broncho-Pulmonary Infections

Evidence gleaned from recent clinical tests suggests notable improvement may be expected in selected cases of bronchial asthma, chronic bronchitis, bronchiectasis, lung abscess, and sinusitis, upon inhalation of Penicillin Aerosol.

The aerosol apparatus illustrated allows rebreathing of the nebulized penicillin solution and increases local deposition of the drug on the broncho-pulmonary surface.

Space does not permit detailed description of this new therapeutic method. The makers of Penicillin Schenley have prepared for the use of physicians, a descriptive folder which is yours for the asking.

Write for our folder describing inhalation therapy with Penicillin Schenley to . . .

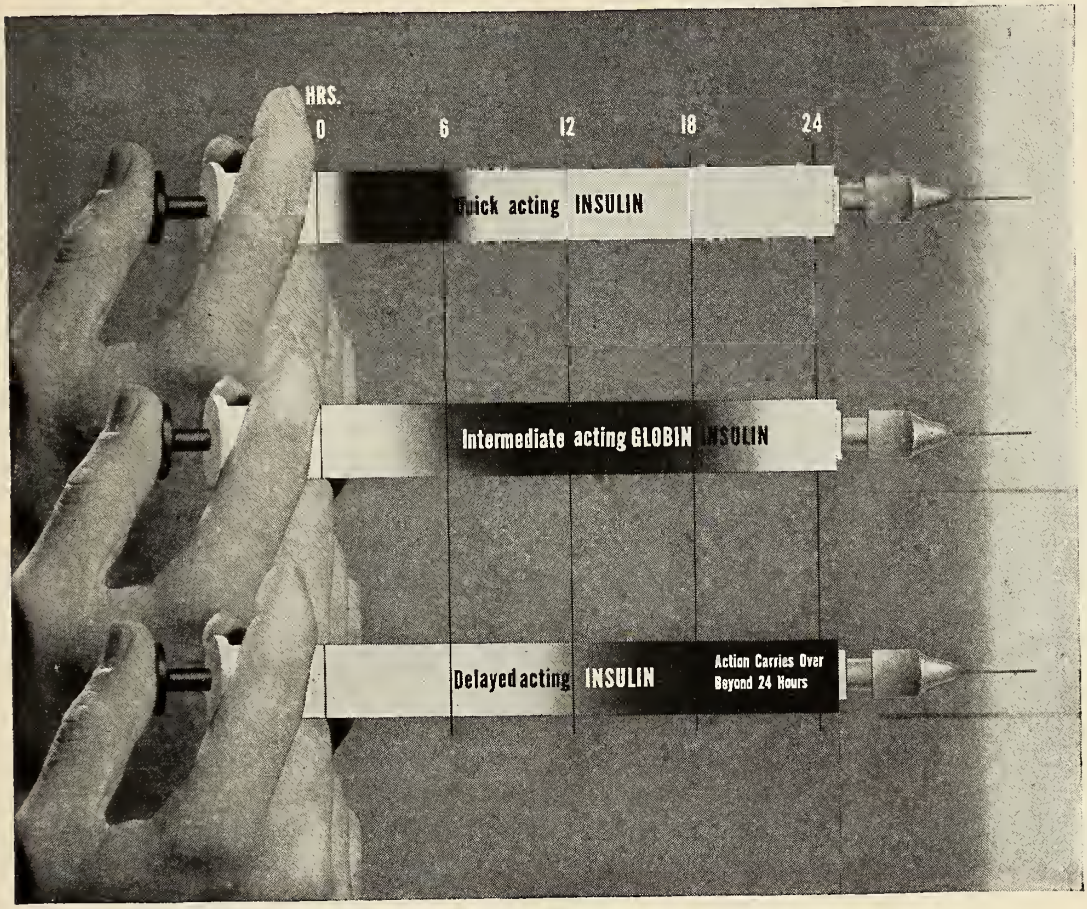
Your 3 choices when treating diabetics...



WHEN A PHYSICIAN decides that a patient needs more than diet to control diabetes, he can now choose from three types of insulin. One is quick-acting and short-lived. Another is slow-acting and prolonged. Intermediate between these, is the third—the new 'Wellcome' Globin Insulin with Zinc. Its action begins with moderate promptness yet is sustained for sixteen or more hours—adequate to cover the period of maximum carbohydrate ingestion. By night, activity is sufficiently diminished to decrease the likelihood of nocturnal reactions. Physicians who consider the many advantages of this new third type of insulin now have another effective method of treating diabetes.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its relative freedom from allergenic properties. Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in the Wellcome Research Laboratories, Tuckahoe, New York. U. S. Patent No. 2,161,198. Available in vials of 10 cc., 80 units in 1 cc., and vials of 10 cc., 40 units in 1 cc. Literature on request. 'Wellcome' trademark registered.

ETHICS

VALIDOS UNIMUS
INVALIDIS SERVIMUS

There can be no middle course between the ethics of the medical profession and the temptations of the market place in the field of anatomical supports. Here the standards of the businessman must be elevated to the standards of the doctor because the customer of the businessman is the patient of the doctor. Anything else is "merchandising quackery." We at Camp have for many decades controlled our distribution throughout the recognized retail institutions which like the doctor have earned the respect and confidence of their home communities. No appeal is used in our advertising approach to the consumer which fails to meet the precepts of the profession. We serve the physician and surgeon by living up to our chosen function of supplying scientific supports of the finest quality in full variety at prices based on intrinsic value. We try to insure the precise filling of prescriptions through the regular education and training of fitters. In cooperation with medical and educational public health authorities we play the role our resources permit in promoting better posture and body mechanics. That is our idea of the practical ethical standards which permit the businessman to solicit the recommendation of the doctor.

Camp Anatomical Supports have met the exacting test of the profession for four decades. Prescribed and recommended in many types for prenatal, postnatal, postoperative, pendulous abdomen, visceroptosis, nephroptosis, hernia, orthopedic and other conditions. If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent upon request.

More pleasure to you, Doctor!

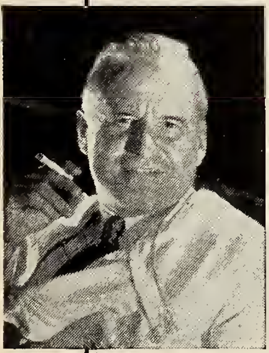
THREE nationally known research organizations recently reported the results of a nationwide survey to discover the cigarette preferences of physicians and surgeons.

Physicians all over the United States were asked the simple question: "What cigarette do you smoke, Doctor?" The question was put solely on the basis of *personal preference as a smoker.*

The thousands and thousands of answers from these physicians in every branch of medicine were checked and re-checked. The result:

More physicians named Camel as their favorite smoke than any other cigarette. And the margin for Camels was most convincing.

Certainly the average physician is busier today than ever before and is deserving of every bit of relaxation he can find in his day-by-day routine . . . a cigarette now and then if he likes. And the makers of Camels are glad to know that physicians find in Camels that extra margin of smoking pleasure that has made Camels such a favorite everywhere.



According to this recent nationwide survey:

More Doctors Smoke Camels

than any other cigarette

The Preference is Overwhelming

A comprehensive report published in *Human Fertility*[1] shows an overwhelming preference by experienced clinicians for the "Diaphragm and Jelly" method of conception control.

The report covering 36,955 new cases shows that the diaphragm and jelly method was prescribed for 34,314, or 93%.

On the evidence supplied by competent clinicians we continue to suggest that for the optimum in protection the physician should prescribe the combined use of a vaginal diaphragm and spermatocidal jelly.

CASE HISTORY

White male, age 62. Severe bilateral varicosities of lower extremities, with cellulitis and thrombophlebitis of right leg. Responded to 30,000 units Penicillin, administered intramuscularly every 3 hours with recovery in 8 days.

PENICILLIN in CELLULITIS

Serious local infections such as cellulitis due to hemolytic streptococcic infections—with or without bacteremia—respond rapidly and dramatically to Penicillin.

Initial dosage of 15,000 to 20,000 units is advised. Constant intravenous injection of an isotonic sodium chloride solution follows, allowing administration of 5,000 to 10,000 units every hour, or 120,000 to 240,000 units in a twenty-four hour period. If this method is found inadvisable, 20,000 to 40,000 units may be injected intramuscularly every three or four hours.*

Bristol Penicillin, because of its low toxicity and freedom from pyrogens, its absolute sterility and standard potency, provides dependable therapeutic action.

For additional current literature on the clinical uses of this potent antibiotic, refer to your issues of the BRISTOL PENICILLIN DIGEST.

Silhouette of Significance

THE PRODUCTION of vitamin products used in modern medical practice involves continual and diversified research. The Lilly Laboratories, besides engaging in pure scientific pursuits and rigid control activities, are especially organized to solve the many perplexing problems of large-scale manufacture. An ever-vigilant scientific staff assures the physician that only the finest materials are used and that finished products are true to label formula. The Lilly Label is profoundly significant. It is the symbol of dependability, a dependability that has made Lilly Vitamin Products the choice of many discriminating physicians. Lilly Vitamin Products are intended for prescription use only and are never advertised to the public.

THE RH FACTOR IN FEEBLE-MINDEDNESS AND OTHER DISEASES

LAURENCE H. SNYDER

Professor of Medical Genetics and Chairman of the Department of Zoology and Entomology
The Ohio State University, Columbus, Ohio

IN recent years much attention has been devoted to the study of the inheritance of various traits, both normal and abnormal, in human beings. Perhaps the most fascinating of these traits are the recently discovered Rh blood types. At first apparently of only theoretical and academic interest, the Rh factors have become of importance in legal medicine, in transfusions, and in the study of infant mortality, and are now extending their influence into the fields of psychology and psychiatry.

In order to understand the Rh factors and their applications, it is necessary to see them in perspective against the background of the human blood groups in general. And in order to understand the genetic and medical applications of the blood groups, it is in turn desirable to view them in perspective against the background of hereditary human traits and their importance in human welfare. Let me then briefly sketch in broad outline the practical applications of human heredity, adding a little more detail when we come to the blood groups, and finally giving very careful consideration to the Rh blood types.

The educated layman is rapidly learning that much information is now available on the mode of inheritance of specific traits in human beings, and he is responding to this awareness by asking questions of his physician, his visiting nurse, his pastor, and other social workers. It behooves those involved in social service to learn some of the answers, and to know where to obtain further information which they themselves may not possess. You in Minnesota are to be congratulated for having available the Charles Fremont Dight Institute for the Study of Human Genetics, which is serving admirably as a clearing house for such information, as well as in a research capacity.

One of the important practical applications of our increasing knowledge of human inheritance is our ability to give genetic advice to families. Parents and prospective parents are often concerned about the future appearance in their children of a trait which has previously occurred in the family. Sometimes it is a desirable trait such as musical ability, curly hair or high intelligence. Sometimes it is an unwanted trait such as diabetes, cleft palate or feeble-mindedness.

Before attempting to answer such a question the consultant must take several steps. He must first make sure of the accurate identification of the trait. This frequently means a medical diagnosis. The ease of identification or diagnosis varies: cleft palate is recognized with relative ease, borderline mental deficiency with considerable difficulty. Frequently, minor variations within a trait must be carefully noted, as they may represent genetic entities.

Having properly described and identified the trait, the second step is to chart the family history of the person seeking advice. This is essential in making an accurate prognosis. The third step is to compare this pedigree with those already re-

---

A public lecture delivered at the University of Minnesota under the auspices of the Charles Fremont Dight Institute and the Minnesota Human Genetics League, November 14, 1945.

corded in the literature or in the files of the consultant, noting the type of hereditary behavior previously assigned to the trait, and paying careful attention to variations in the expression of the trait, the age of onset, and the regularity with which the character has appeared.

Last, the potential effects of the environment on the trait must be reviewed, and the probable environment in which the trait will develop if it appears in this family must be specified.

With the foregoing information available it may be possible to give a reasonable estimate of the probability of the recurrence of the trait.

A few personal instances may be permissible as illustrations. I was recently consulted by a man who had suffered all his life from brittleness of bones, fractures occurring at the slightest provocation. The sclerotic coat of the eyeball was pale blue. His mother had had the same blue sclerotics, but with less marked tendency to fractures. He wished to marry, and wondered whether the trait might reappear. Since it is known to be transmitted as a dominant factor, it was necessary to inform him that he might expect the condition in about half his children, both boys and girls.

I was asked to advise a young couple who had lost their first child from the infantile form of amaurotic idiocy. This is a condition in which mental failure, paralysis, blindness and finally death occur in infancy. The diagnosis had been made by a competent physician. The mode of inheritance of this condition is known to be that of an autosomal recessive factor, unaffected by ordinary environmental influences, so that the parents were notified that the chances of another child having the disease were one in four. In this instance the parents felt that they were emotionally unable to stand another strain like that imposed by the slow death of the first child, and decided to adopt a child.

Very recently there appeared at the Ohio State University Hospital two brothers, aged nine and eleven, suffering from pseudohypertrophic muscular dystrophy. The parents had come to appreciate the hopeless outlook for the affected boys, but wanted particularly to know the chances that the condition would reappear if the normal brothers and sisters should marry. Since the dystrophy is the result of a sex-linked recessive factor, it was possible to advise them that the normal boys in the family could not possibly transmit the defective gene, but that the girls had an even chance of carrying it and thus of producing affected sons.

A short time ago I was asked to see a young couple who had a male infant suffering from a condition known as epidermolysis bullosa of the dystrophic type. In this form of the abnormality the skin becomes blistered wherever subjected to friction, the blisters occurring between the epidermis and the corium. They become malignant, and death usually occurs in infancy or childhood. The nails and teeth are affected, and the blisters occur in the mucous membranes as well as in the more usual places. The parents wanted information as to future children. This type of epidermolysis is due to an incompletely sex-linked gene, so that a still different prognosis must be made. Since the affected child was a boy, other affected children in this family are likely to be boys, although occasionally an affected girl might occur. With a known crossover value of twenty per cent for this trait, a girl in this family would have only one chance in ten of being affected, while another boy would have nearly one chance in two (four in ten) of having the epidermolysis.

The foregoing instances are all examples where sufficient information on the genetics of the trait was available to make accurate prognosis possible. In many diseases and abnormalities, accurate genetic data are not at hand and explicit information cannot be given. There is crying need for more and more research in medical genetics and human heredity.

One of the most important practical applications of our knowledge of human genetics is in the field of preventive medicine. It is becoming more and more feasible to prevent, in the relatives of persons with genetic conditions, the appearance of the abnormality or disease. It is done by instituting preventive measures, on the basis of the genetic history. The procedure is to examine the relatives of an affected patient for the early pre-clinical or laboratory signs of the trait, and then to take such precautions in those who show the signs as will minimize the danger. The preventive splenectomy in hemolytic icterus is a brilliant example of such procedures, and many others could be cited.

To take a personal instance, we were recently able to suggest such preventive measures in a family in which several members suffered from xanthoma tuberosum. This, like the amaurotic idiocy previously referred to, is a storage disease, a lipoidosis. In contrast to amaurotic idiocy, however, there are pre-clinical laboratory signs which may be discovered in time to prevent any fatal consequences. The visible signs of the abnormality are nodules and tumors of the joints and tendons. The hidden symptoms are increases in the blood cholesterol and cholesterol esters. In contrast to a normal blood cholesterol of 150-300 mg. per cent, the value in xanthoma may reach 1500 mg. per cent. The disease may progress to cardiovascular involvement with sudden death.

Since the increase in blood cholesterol is transmitted as a dominant factor, and since it may occur long before the appearance of the nodules and tumors, it is feasible to examine the relatives of patients with nodules by determining their blood cholesterol and cholesterol esters. Where hypercholesteremia is found, preventive dietary measures may be instituted, thus helping to preclude cardiovascular involvement and possible death.

Another important set of practical applications of human genetics occurs in medico-legal cases as a consequence of our knowledge of the human blood groups. In the early days of this century Karl Landsteiner discovered that when the red cells of one person were mixed with the serum of another person, a reaction sometimes occurred. The red cells were clumped, or agglutinated, by the serum. This did not happen in all mixtures of serums and cells, but only when the cells of certain persons were mixed with the serum of certain other persons. Landsteiner recognized that the reaction was that of antigen with antibody; that is, the red cells of some people contain an antigen, and the serum of some others contain the corresponding antibody. Upon mixture of the antigen and the antibody, agglutination results.

Further work by Landsteiner disclosed the fact that there were two such antigens in human blood, and these he named A and B. There are thus four kinds of people in the world: those containing antigen A in their cells (hence spoken of as belonging to group A), those containing antigen B (group B), those having both antigens (group AB), and those having neither antigen (group O).

There is a reciprocal relationship between the antigens and the antibodies in the A-B series, since everyone has either antigen A or the antibody against A, and everyone has either antigen B or the antibody against B. There are thus natural or "normal" antibodies against A and B available in the bloods of various individuals.

TABLE I. MAJOR LAWS PERTAINING TO MEDICO-LEGAL APPLICATIONS OF BLOOD GROUPS AND TYPES

1. Agglutinogen A, B, M, N, P, Rh or Hr cannot appear in a child unless it was present in one or both parents.
2. Water-soluble agglutinogen A or B (as opposed to alcohol soluble) cannot appear in a child unless one or both parents had the "secreting" ability.
3. A parent of group AB cannot give rise to a child of group O.
4. A parent of type O cannot give rise to a child of group AB.
5. A parent of type M cannot give rise to a child of type N.
6. A parent of type N cannot give rise to a child of type M.
7. A parent lacking a particular Rh agglutinogen cannot give rise to a child lacking the corresponding Hr agglutinogen.
8. A parent lacking a particular Hr agglutinogen cannot give rise to a child lacking the correspondeing Rh agglutinogen.

The first obvious importance of this discovery was to transfusion, since it would not do to give red cells to a person whose serum would immediately clump these cells. Hence in all transfusions the blood groups of donor and recipient must be determined, and compatible blood given.

The fact that there were four kinds of people who could be classified in this way was of immediate interest to the geneticist. In our own laboratory and those of other investigators researches were quickly undertaken to determine how the blood groups were inherited. The study of many thousands of families has made it clear that antigen A never appears in a child's blood unless it was in the blood of at least one of the parents. Similarly, antigen B never appears in a child's blood unless it was present in the blood of at least one of the parents. Other more complicated laws can also be stated, which need not be gone into in detail here (Table I).

Although these facts were at first merely of academic interest, they proved very quickly to be of practical importance. They may be used, for example, in cases of disputed parents. If a child, for instance, is of group B, and the mother is of group O, then we know that the child inherited antigen B from its father. If the alleged father should be of group O or of group A, we can say definitely that he is not the true father of the child.

Antigen A was later found to occur in three grades, so to speak. These have been namd A_1, A_2 and A_3. There are thus actually eight different groups in the A-B series, namely O, A_1, A_2, A_3, B, A_1B, A_2B, and A_3B.

You will recall that antigens A and B were discovered because of the presence in human serums of naturally occurring antibodies against them. In 1927 it occurred to Landsteiner and Levine that there might be still other antigens present in blood cells for which there were no normal antibodies. Such antigens might be discovered by injecting human red cells into animals, in which case the animals would produce antibodies against any specific antigens present in the cells. Accordingly they injected group O cells into rabbits, removed the heterologous antibodies, and discovered that the rabbits had produced specific antibodies against several antigens not previously recognized in human blood cells.

Two of these newly discovered antigens were named M and N. They were found to be related in such a way that a person might have one of them in his cells, or the other, or both. No one has been found who lacks both M and N. In inheritance studies, it was found in our laboratory and others that these antigens, like A and B, are dominant, and do not appear in a child's blood unless they were present in the blood of at least one of the parents. Like antigen A, antigen N comes in more than one grade. Thus N_1 and N_2 are recognized, and there are five types in the M-N series, as follows: M, N_1, N_2, MN_1, MN_2. Within the A-B series, it will be recalled, there were eight kinds. Since any one of those eight could be any one of the five M-N types, there are 8 x 5, or 40 different groups in these two series taken together.

Not only do antigens M and N lack normal antibodies, but they are only very weakly antigenic to human beings. Hence they are of no importance in transfusions, since even multiple injections of M into a person lacking it, or of N into a person lacking it, will not produce strong antibodies, such are produced by injection into rabbits. The chief importance of antigens M and N is in their medicolegal applications, in disputed paternity cases (Table I).

Another antigen was found in the course of the foregoing studies of Landsteiner and Levine. This antigen was named P, and is inherited independently of antigens M and N. It is less satisfactory to use in medicolegal studies than the other antigens, since potent sera are difficult to obtain and standardize, and the reactions are graded. Certain normal animal sera have been found to be fairly good sources of anti-P, particularly pig serum. Like the previously mentioned antigens, P does not occur in a child's blood unless it was present in the blood of at least one of the parents. Moreover, P also appears to occur in two grades, P_1 and P_2, so that four kinds of persons can be classified when proper antisera are available, namely, P_1, P_2, P_1P_2, and P—.

It will be recalled that in the combined A-B and M-N series there were 40 different types of human blood. Since any one of the 40 could be any one of the 4 types in the P series, there are altogether 40 x 4, or 160 types, using all the antigens so far discussed.

In the years between 1930 and 1933 various investigators demonstrated that antigens A and B occur in two main chemical forms: alcohol-soluble and water-soluble. Thus persons of groups A, B, and AB may develop water-soluble antigens, in which case the group-specific substance is found in the body fluids (saliva, tears, urine, milk, etc.) as well as in the cells. Or they may develop alcohol-soluble antigens, in which case the group-specific substance is restricted to the blood cells and tissue cells. Schiff and his coworkers have designated those persons having water-soluble antigens as "secretors," those having alcohol-soluble antigens as "non-secretors." By means of special techniques even individuals of group 0 can be classified into secretors and non-secretors.

The water-solubility of antigens A and B, that is to say, the "secreting" ability, is inherited on the basis of a dominant factor. When both parents are non-secretors, all the children are non-secretors. These factors may thus be added to these previously used in medicolegal applications (Table I). In addition, they double the number of recognizable blood types. Using antigens A, B, M, N and P, we have already classified 160 types. Since any one of these 160 types could be S+ (secretor) or S— (non-secretor), there would be 160 x 2, or 320 types thus far classifiable.

We have now set the stage for the discussion of the Rh blood types, which fit into the picture at this point.

Further attempts at discovering still more human blood antigens by injection of human blood into animals gave disappointing results. Landsteiner and Wiener therefore tried a somewhat different approach. In 1940 they injected blood from the monkey, *Macacus rhesus*, into rabbits. The rabbits responded by producing an antibody against rhesus blood. When this antibody was tested against human blood, it was found to agglutinate the cells of about 85 per cent of white individuals. Thus 85 per cent of us share an antigen in common with rhesus monkeys, and 15 per cent of us do not. This antigen is different from A, B, M, N or P. Using the first two letters of "rhesus," the antigen was named Rh. Persons having the new antigen were designated Rh positive (Rh+), while those not having it were designated Rh negative (Rh—).

TABLE II. HUMAN BLOOD GROUPS

System	Groups	Classes
A-B-O	O, A_1 A_2, A_3, B, A_1B, A_2B, A_3B	8
MN	M, N_1, N_2, MN_1, MN_2	5
P	P_1, P_2, P_1P_2, P–	4
S	S+, S–	2
Rh	Rh°, $\mathrm{Rh}^{\circ\prime}$, $\mathrm{Rh}^{\circ\prime\prime}$, $\mathrm{Rh}^{\circ\prime}\mathrm{Rh}^{\circ\prime\prime}$, $\mathrm{Rh}^{\prime}$, $\mathrm{Rh}^{\prime\prime}$, $\mathrm{Rh}^{\prime}\mathrm{Rh}^{\prime\prime}$, Rh–	8

8 × 5 × 4 × 2 × 8 = 2,560

Studies on the inheritance of the Rh antigen showed that it too was inherited as a dominant factor, and that it never appeared in a child's blood unless it was present in the blood of at least one of the parents. It therefore takes its place with the other antigens in medico-legal applications (Table I).

There are no normal antibodies against antigen Rh in human serums. In this respect the situation is similar to that in regard to M and N. Unlike antigens M and N, however, Rh is highly antigenic to human beings. Repeated injection of Rh+ blood into an Rh— person results in immunization of the recipient, and transfusion reactions of increasing severity. It is essential, therefore, to transfuse Rh— blood into an Rh— person. For even though the first transfusion might cause no reaction, the immunization process would be initiated, and a subsequent transfusion might be fatal. While only a small proportion of transfusions in civilian practice is made up of multiple transfusions, this proportion rises in military medicine to 80 per cent.

The Rh antigen has another unique property. It is capable of passing from the fetal circulation through the placenta into the maternal circulation. This fact led to another important discovery, namely, the cause of the disease known as erythroblastosis.

Erythroblastosis is a disease of the fetus or newborn infant, characterized by anemia, jaundice, congenital hydrops, and sometimes stillborn macerated fetuses. In 1939 Levine and Stetson studied the blood of a mother who harbored a macerated fetus, and found that it contained an atypical antibody. They postulated that the mother had been immunized by her own fetus, and the resulting antibody had caused the destruction of the fetus. The following year Landsteiner and Wiener announced the discovery of the Rh factor, and this quickly proved to be the agent postulated by Levine and Stetson.

Levine, Katzin and Burnham in 1941 showed that the Rh antigen was indeed the primary cause of erythroblastosis fetalis. In nearly all cases of the disease, the mother proved to be Rh—, the fetus Rh+. The Rh antigen in the fetus was, of course, inherited from the father. The Rh— mothers can be shown to have developed antibodies against Rh. Apparently the Rh antigen has passed through the placenta into the circulation of the mother, immunized the mother, and the maternal immune antibody has then passed back into the fetus, damaging the red blood cells. The result is hemolytic jaundice and other effects. While the test-tube reaction is agglutination, the end result in the fetal circulation is hemolysis. The regenerative activity of the fetal blood-forming system floods the circulation with immature red cells (erythroblasts), hence the name erythroblastosis.

Ordinarily the first Rh+ child born to an Rh— mother is itself unaffected, since the production of antibodies by the mother has not reached a high titer by the time of the birth of the infant. A second Rh+ embryo, however, stimulates the further rapid production of antibodies, and this and all subsequent Rh+ fetuses will be affected. Occasionally a woman produces antibodies so readily that even the first Rh+ embryo may be affected. Of course if an Rh— woman has received a transfusion of Rh+ blood previous to her first pregnancy, she will already have been immunized, and the first Rh+ fetus she carries can be affected by the antibodies.

On the other hand, some women produce antibodies so slowly that several Rh+ fetuses may be required before one becomes erythroblastotic.

Although anti-Rh serum was originally obtained from rabbits immunized with rhesus monkey blood, and later from immunized guinea pigs, it was soon found that the serum from mothers of erythroblastotic infants was a much better source of test antibodies than serum from immunized animals. Such mothers are the present source of test serums. In studying human serums from immunized mothers, several new kinds of anti-Rh antibodies have been discovered, making it possible to identify corresponding new kinds of Rh antigens.

Shortly after the description of the original Rh antibody, Wiener found a human serum which agglutinated only 70 per cent of human bloods, but which was related to the original anti-Rh serum, since bloods negative to the one were usually negative to the other. The original antigen is now called Rh° (or Rh_0), and the new one is called Rh′. Levine then found a serum which agglutinated about 87 per cent of human bloods, and obviously contained both antibodies, that against Rh° and that against Rh′. Some persons are found to have Rh° in their red cells, and some to have Rh′. In addition, some persons have both, and this may be the result of their inheriting two genetic factors, one for each antigen, or of their inheriting a single genetic factor (*Rh°′*) accounting for both.

Still later Wiener discovered a third type of human antiserum which reacted with but 32 per cent of human bloods. The antigen corresponding to this antibody was named Rh″. Using the three antiserums, eight kinds of people may be distinguished, as follows: Rh°, Rh′, Rh″, Rh°′, Rh°″, Rh′Rh″, Rh°′ Rh°″, and Rh—. The first seven of these eight types are Rh+ for one or more of the Rh antigens; the last one is Rh negative.

We had already distinguished 320 kinds of people based on A, B, M, N, P and S. Since any one of the 320 could be any one of the eight Rh types, we can now distinguish 320x8, or 2,560 types, using all the known factors (Table II). Of course some of the types are far commoner than others in the population, and some of the antiserums are difficult to obtain in standard form. Nevertheless, with the proper antiserums it would be possible to take a small sample of blood from each one of you in the audience, and in a short time to place each of you in your own blood type. It would be surprising if any two of you were in the same type. Ten years from now it would be possible to take another sample of blood from each of you, and without having the samples individually named, to assign each blood to a specific person by referring to the previously recorded data, except for such duplications of type as might exist among you.

Using all the Rh factors, 87 per cent of American whites are Rh+ and only 13 per cent are Rh—. Taking these figures, we may compute how often Rh— women will marry Rh+ men by chance in the general population, and how often such marriages should result in Rh+ children, who might thus have erythroblastosis. Let us for this purpose consider all the Rh antigens collectively, as Rh+, contrasted with Rh—, in which none of the antigens is present. Since hereditary factors occur in pairs in an individual, an Rh+ man might be *RhRh* or *Rhrh*. In the first instance he is said to be pure or homozygous for the Rh factor, and can transmit only the factor for the antigen to his children. In the second instance (*Rhrh*), he is hybrid, or heterozygous, and will transmit the factor for the Rh antigen to only half his children. Rh— women are all homozygous *rhrh*.

By appropriate statistical methods of gene-frequency analysis, we can show that in the general population 41 per cent are *RhRh*, 46 per cent are *Rhrh*, and 13 per cent are *rhrh*. Thus Rh— women will marry Rh+ men in 11.3 per cent of all matings. But 5.33 per cent (13 per cent of 41 per cent) will be with homozygous men, and 5.98 per cent (13 per cent of 46 per cent) will be with heterozygous men. All the offspring from homozygous men will be Rh+, but only half of those from heterozygous men will be Rh+. Therefore 5.33 per cent + ½ of 5.98 per cent of all children born will be Rh+ children from Rh— mothers. This figure is 8.32 per cent. We should expect to find erythroblastosis, then, in 8.32 per cent of all births, that is, about one in twelve. However, the frequency of clinically diagnosed cases has never approached this figure. The recorded incidence is about one half of one per cent; or about one in 200 births. Why does this discrepancy between the calculated and the observed proportions occur?

First of all it must be remembered that firstborn children are seldom if ever affected. In the American population, the average number of children in families having at least one child is 3.24. This means that one out of 3.24, or about 31 per cent of children born in this country, are firstborn. This reduces the expected proportion of children showing the effects of the immunization of the mother by the Rh factor to 5.74 per cent. Thus we would expect only about one in seventeen to show the effects. This closes somewhat the gap between expected (1 in 17) and observed (1 in 200), but still leaves a considerable discrepancy.

The cases of erythroblastosis are not distributed at random among the potential Rh— mothers, but usually occur several in the family. It may be, then, that only some women are capable of producing potent antibodies against the Rh antigens. It may also be true that the antigen gets through the placenta only in some Rh— mothers. Perhaps both of these phenomena account for some of the discrepancy between calculated and observed incidences of erythroblastosis.

It is also conceivable, however, that in some instances where the antigen penetrates the placental barrier, and the antibodies in turn reach the fetal circulation, that the effects on the fetus are different from those recognized as classical erythroblastosis.

In various laboratories, including our own, the search has been made for such manifestations. The effects of Rh immunization appear to be unimportant in the production of early abortions, and in the etiology of hemolytic icterus, sickle cell anemia, hydatiform mole, ectopic pregnancies, eclampsia and specific toxemia.

In 1944, Yannett and Lieberman made an examination of the blood groups and types of the children in a school for the feeble-minded, and of their mothers. There were too many Rh— mothers in the group, and too many Rh+ children of Rh— mothers. Breaking down the results it was found that of 109 feeble-minded children, fifty-three were distributed among the specific types of mental deficiency such as Mongolian idiocy and spastic paraplegia. The distribution of the Rh factor was normal in these children and in their mothers.

In the fifty-six children classified as undifferentiated mental deficiency, however, an abnormal distribution of the Rh factor was found. There were too many Rh— mothers and too many Rh+ children from these Rh— mothers.

These results appeared to us so suggestive that we have been investigating the blood of the undifferentiated feeble-minded at the Ohio Institution for the Feeble-minded, and of their mothers (Snyder, Schonfield and Offerman, 1945). The complete results up to date are as follows: Of 169 mothers of feeble-minded children, thirty-eight are Rh—, whereas only twenty-one or twenty-two would be expected. This difference is statistically highly significant. Of 171 feeble-minded children, twenty-seven are Rh+ from Rh— mothers, whereas we should expect only fourteen. This deviation is also highly significant when tested statistically.

Thus it would seem that in some instances the immune antibodies of the mother produce effects on the brain tissue instead of the usual effects recognized as erythroblastosis. It has been suggested that the immediate effect of red-cell destruction is anoxia, and that this lack of oxygen, if it occurs at a time when the brain of the embryo is in a critical stage of development, may very well cause permanent mental deficiency.

Thus the gap between the calculated incidence of effects of Rh immunization and the observed incidence has been partially closed up. However, the search must continue for further, as yet unknown, manifestations. In our laboratory we have recently completed an analysis of a large number of cases of dementia praecox and their mothers. The distribution of the Rh factors is perfectly normal in these instances.

It might seem surprising that heterospecific pregnancies in regard to antigens A and B play no part in erythroblastosis, since antibodies against A and B are normally present in bloods lacking these antigens, and would not even have to be stimulated by immunization. The explanation seems to be that antigens A and B, at least in secretors, are found in all tissue cells and body fluids, including the amniotic fluid and secretions of the fetus. This may serve to protect the fetus from antibodies against A and B. On the other hand, antigen Rh seems to be restricted to the red cells, and such a protective mechanism cannot operate. There is, however, some evidence that incompatibility of A and B can cause mild symptoms in cases where the fetus has one of these antigens which is lacking in the mother. Mild

TABLE III. GENETIC BASIS OF THE RH BLOOD TYPES, SHOWING REACTION OF EACH TO RH AND HR ANTISERA.
(Frequencies given are for American Whites)

Rh° also called standard Rh
Rh°′ also called Rh_1
Rh°″ also called Rh_2

jaundice of group A infants from group O mothers has been reported by Polayes (1944). In these cases the titer of anti-A antibodies was found to be 1:700 as compared with an average of less than 1:200.

At first glance it might appear that the death of erythroblastotic infants is gradually eliminating the *Rh* factor. Actually it is the other way around, and the *rh* factor is being eliminated instead. This is due to the fact that every erythroblastotic infant is heterozygous, *Rhrh,* so that each death removes equal numbers of the two genes. Since there are far more *Rh* genes than *rh* genes in the world, a larger proportion of the *rh* genes is lost each time.

The mechanism of the immunization of the mother has been discussed by various workers (cf. Levine 1944). It is assumed that in every normal pregnancy minute quantities of blood from the fetus may find their way into the maternal circulation through microscopic breaks in the villi of the placenta. Very small amounts of blood are necessary for immunization. When it is realized that the total area of villi exposed in the placenta to the maternal circulation is 70 square feet, and that these villi, if extended in a straight line, would reach eleven miles (Dodds 1922), it is not hard to imagine the availability of microscopic amounts of fetal blood to the mother.

The feeble-mindedness due to Rh incompatibility is an acquired mental deficiency, and cannot of course be transmitted to offspring. It could thus account for some of the isolated cases of undifferentiated feeble-mindedness in otherwise highly intelligent families, and also for some of the instances where two feeble-minded parents have produced normal offspring. Perhaps not more than 10 per cent of all undifferentiated mental deficiency can be attributed to Rh incompatibility. The mere fact that it occurs, however, means that when an Rh— girl marries an Rh+ man, she is exposing herself not only to the risk of stillborn or erythroblastotic children, but of mentally deficient children as well.

While these facts are not cause for undue alarm, it would seem advisable that every girl, on entering into marriage, should learn her Rh type and that of her husband. If she is Rh+ (as seven out of eight will be) she has nothing to worry about. If she is Rh— and marries an Rh— man, she still has no cause for worry. But if she is Rh— and marries an Rh+ man, she should inform her family physician of this fact, so that he may take all available precautions for the preservation of any Rh+ infant she might have.

Recent discoveries have brought both new dangers and new hopes. I refer to the newly described Hr factors (Hr is Rh in reverse). Once in a great while an Rh+ mother has an erythroblastic child. The danger is very small indeed, but the hopes aroused by this discovery are great. In these cases the effect is that of the Hr factor. The Hr factor is reciprocally related to the Rh factor. Corresponding to the three Rh antigens, Rh°, Rh′ and Rh″, three Hr antigens, Hr°, Hr′ and Hr″ are postulated. Two of these, Hr′ and Hr″ have been discovered and described; the third will no doubt soon be found. The reactions of the blood types with Rh and Hr antiserums are shown in Table III.

The rare cases of an erythroblastotic child born to an Rh+ mother are cases where the mother is Hr— and the child is Hr+. The Hr— mother and the Hr+ child must both be Rh+, since as shown by the table an Hr— mother cannot be heterozygous for *rh*. The father may be of any Rh type, since Hr+ individuals occur in all Rh blood types.

The hopes aroused by this new discovery are that by the use of anti-Hr serums we may be able to pick out, in some instances at least, heterozygous Rh+ men. This would be of value because such men, when married to Rh— women, could expect half their children to be Rh— and therefore free from effects of the incompatibility, whereas homozygous Rh+ men cannot produce Rh— offspring.

Using antigen Hr′, there are ten kinds of Rh types instead of eight, as may be seen from Table III. There would thus be 3,200 different types classifiable instead of 2,560. Using all three Hr antigens when they become available, we shall have eighteen Rh types, and thus 5,760 blood types altogether. Looking into the future, the final result staggers the imagination. The specificity of human blood is a fascinating subject for research.

The Hr antigens are very new to us as yet, and are at present only partially understood. It is obvious that much detailed research work remains to be done on this and other phases of the problem. Basic research in chemistry, physics, biology and medicine will all contribute to its solution. The problems involved are primarily problems of medical genetics, however, and can be solved only by those trained in medicine and in genetics, working in co-operation. May I take this opportunity to point out the very valuable potentialities of integrated groups like those working at the Dight Institute, and may I urge you all to give your fullest support to such programs of research and education as they are carrying out.

MASS X-RAY SURVEYS

The results of mass x-ray surveys in discovering unsuspected tuberculosis in apparently healthy persons lead one to the logical assumption that just as much, and probably more, tuberculosis might be found through routine roentgenological examination of patients admitted to our general hospitals and clinics. The Mayo Clinic has had such a program for a number of years. At the University of Chicago Hospital and Clinics where this procedure has been followed since 1939, 1.43 per cent of those examined have shown clinically significant tuberculosis. In addition, a large number of nontuberculous chest conditions were found. The most important among these were malignant neoplasms and cardiovascular disease. The over-all percentage of pathological findings was 21.2 per cent.—Karl H. Pfuetze, M.D., Med. Dir. & Supt., Mineral Springs San., Cannon Falls, Minn.

SEROLOGY AND OBSTETRICS

R. T. La VAKE, M.D.
Minneapolis, Minnesota

THE purpose of this paper is to discuss the accumulating obstetrical serologic evidence that suggests: that the definition of the A, B, and Rh antigens as merely agglutinogens is inadequate; that in humans their essential property is that of toxins when they can gain access to a host that does not possess them by inheritance; that in the manifestations of pregnancy toxemia we are witnessing the effects in the host of one or more of these toxins, whereas in erythroblastosis and some fetal deaths and abortions, we are witnessing the effects of corresponding specific antitoxins, generated or inherited by the host.

Though an obstetrical topic, the practical bearing of the evidence on the problems of safe blood transfusion is of importance to all.

Clinical and pathological data have increasingly converged in proof upon the fetal toxin hypothesis of pregnancy toxemia. Data have been furnished by Veit, in 1902; Dienst, in 1905; James Young, in 1914; McQuarrie, in 1923; Ottenberg; and Bartholomew and Colvin; to name but a few investigators. These data, though raising the probability of the fetal toxin hypothesis was not conclusive evidence. To be conclusive, a clearly identifiable toxic substance or antigen must be demonstrated in the fetus, and a corresponding antitoxin or antibody in the mother, and a functional relationship between them must be demonstrable, precisely as obtains in bacterial toxemia or snake venom poisoning.

The serological approach to the pregnancy toxemia problem was unsatisfactory until Jonsson, in 1936, showed that by titering the maternal group antibodies one could often predict the group of the child by the rise above average of the titer of the maternal antibody involved. For example, in a group O mother, with a group B husband, if the B antibody titer rises above average, it allows one to predict with fair accuracy the B status of the child. It has been in such cases where the maternal antibody titer rises that the obstetrician has been finding the manifestations of toxemia. One logical interpretation is that the rise of the titer is a manifestation of an antitoxin response to its corresponding toxin. This seemed like valid reasoning, but how could one account for the cases of toxemia in which no A or B incompatibility existed between child and mother? This had been an insistent question since the beginning of this work in 1919. Possibly the toxin was more fundamental than could be demonstrated by blood group incompatibility. Possibly men were correct in maintaining that the A and B substances were merely agglutinogens and non-toxic antigens. To throw some additional light on the problem, a maternal skin test was devised for toxemics, which, like the Mantoux test for tuberculosis, was interpreted as showing that whatever the nature of the toxin, a toxin existed, and in pregnancy toxemia the mother was immunized to that particular toxin. It seemed to aid in the proof of the toxin hypothesis, but it in no way identified the toxin and could only be used after the birth of the child.

Then came the discovery of the so-called Rh factor by Landsteiner and Wiener, followed shortly by the work of Levine, Katzin and Burnham, showing the relationship between this factor and erythroblastosis fetalis, abortions, stillbirths and macerated fetuses. To the investigator of the toxemias of pregnancy, these discoveries took on a much wider significance than was manifest in their obvious importance in blood transfusion and erythroblastosis. The discovery of the Rh factor furnished a possible answer to the insistent question above referred to, and the work on erythroblastosis furnished further evidence in the fetal toxin argument by completing the missing arc of the circle of the classical and accepted toxin-antitoxin mechanism. If the incompatible fetus, which is a colony of genetically regimented cells, each containing a toxin specific to that mother, could suffer injury and death from the mother's specific antitoxin, then it would be unreasonable to support a belief that the maternal organism could emerge without showing signs of injury. The maternal manifestations must be ascribed to the action of the

---

Read before the Minnesota Academy of Medicine, November 14, 1945.

toxin, as in bacterial or snake venom poisoning. At first, the Rh factor held the field, but it soon became apparent that the A and B antigens could bring about erythroblastotic injury and disaster where the Rh status of the husband and wife were similar. All this data irresistibly leads the obstetrician to the conclusion that the only adequate definition of the A, B, and Rh antigens must be that they are toxins. That is their essential property. The relationship of the fetus to its mother is a toxin-antitoxin relationship, when the fetus possesses one or more of these toxins and the mother does not. The results depend upon whether these toxins can gain access to the mother, the amount of the insult, and the reactive properties of the maternal organism.

At first it was perplexing to note that only about 30 per cent of the erythroblastosis cases showed gross signs of pregnancy toxemia. If only 30 per cent showed signs of toxemia and 70 per cent did not, perhaps the men were correct who ascribed all the manifestations of toxemia to the cardio-vascular-renal setup. The advocates of the fetal toxin hypothesis had always held that the cardio-vascular-renal setup played the role of the soil upon which the toxic pregnancy was implanted. It functioned as a conditioning agent but not as a cause. Were we overlooking subclinical toxemia in the missing 70 per cent? It suggested itself that the same law might function here as in snake venom poisoning, namely, that, all things being equal, the manifestations of poisoning in the host vary directly with the strength and amount of the toxin, and indirectly with the strength and amount of the antitoxin generated in the host, or given artificially. A study of maternal antibody titers in the past five years is highly suggestive of the similar functioning of this very law. If one will follow the specific antibody involved in any toxemia, one will see that when the titer remains comparatively low, the manifestations of toxemia are the most severe. After delivery, upon separation of the fetus with its antibody absorptive power, the maternal antibody titer will jump to many times its antepartum strength, with a rapid subsidence of the toxic manifestations. The highest jumps occur in cases of erythroblastosis in which the mother has shown no evidence of toxemia. The interpretation here is that the antibody or antitoxin absorptive power of the fetus keeps the maternal antibody titer comparatively low, but high enough to protect the mother and yet it is high enough to injure or kill the fetus.

Antibody studies suggest that a toxin-antitoxin basis forms the link between late toxemia and premature separation of the placenta. This basis furnishes the only reasonable explanation for certain types of onset and for some of the bizarre findings at times exhibited where for any reason the abdomen has been opened in cases of toxemia or premature separation. One of the interesting features of this serologic approach is that you can check back for years over your outstanding cases if the mothers and children are available.

The following of antibody titers also brings out another suggestive finding. A titer will run along on a virtual level, when, with the accession of an acute infection, the titer will jump from ten to twenty times its former strength, remain there during the infection, and then return to its preinfection level. This finding furnishes one rational explanation for the 40 to 50 per cent correlation between severe infection and death of the fetus and abortion. Although fetal red cells, as shown by Kemp, are five times less vulnerable to antibody agglutination than are adult cells (and one should thus be able to predicate logically that all the fetal cells are in this proportion protected from the deleterious effects of any antibody) if, by infection, any antibody strength were disproportionately raised, the possible results to the fetus would be obvious. Clinical observation suggests that not alone by direct action is the fetus killed by the maternal antitoxin, but indirectly through placental infarction. The placenta is the first line of defense in the toxin-antitoxin battle, and it would appear that infarction is a consequence of toxin-antitoxin action. This would explain the high correlation between the finding of gross infarction and late toxemia, and, in relation to infection, the finding of outstanding infarcts that it has been claimed can be estimated as having taken place during the time of the infection.

It would seem that in the light of present-day serologic and obstetrical data, the A, B, and Rh antigens must be redefined as toxins. When any one or more of these toxins reside in the fetus and can gain access to a mother not possessing them, the symptoms, signs and pathology of pregnancy toxemia supervene. The outcome depends upon the toxicity of the antigen and the reactive properties of the mother. The anatomic structure of the attachment of the fetus to the mother is such that at times a slight blood spill from fetus to mother can take place. When and if this occurs, the property of the antigen as an agglutinogen tends to bring about placental infarction and a sealing of the leak. Any clumping of the comparatively few fetal red blood cells in the maternal blood stream is merely a harbinger of approaching death and dissolution of the fetal cells under antitoxin attack, as obtains with bacteria. The disintegration of the fetal red cells merely increases the toxic content already in the serum. At no time is the picture similar to gross transfusion or to the experiments that conditioned the original definition of the A and B antigens. In the gross transfusion of incompatible blood, the A, B, or Rh antigens involved likely act as toxins as in pregnancy toxemia, but massive agglutination and other hemolytic processes kill the patient before this toxic action can manifest itself. The autopsy manifestations of the toxic action are obscured by the gross agglutination and breaking down of the transfused cells. In pregnancy toxemia, on the other hand, the autopsy findings give a clear picture of the effects of the toxin working over comparatively longer periods of time.

Our time limit on papers does not permit a consideration of the practical application of this material in the management of pregnancy toxemia or erythroblastosis, but it does permit a most important reference to the demands of safe blood transfusion, and the demands of protecting the childbearing possibilities of some women.

If a women is Rh negative, we must always consider the possibility of isoimmunization in even the first transfusion, if she is pregnant or has ever been pregnant. More important still is the responsibility resting upon us all to use Rh similar blood in the transfusion of all females to prevent the possible consequences of isoimmunization. It has been studiously estimated that transfusion is ten times more likely to isoimmunize a woman than is a pregnancy. Failure to follow this injunction may, at any time before menopause, destroy a woman's future ability to bear viable children. The frequency of transfusion is increasing by leaps and bounds in the interests of therapy, and in the fulfillment of these interests its use, as yet, comes far from having reached the saturation point.

The titer data upon which this paper is largely founded resulted from a determined effort on the part of many obstetricians, pediatricians, and general practitioners in the Middle Northwest to solve the problems involved in erythroblastosis fetalis, and safe blood transfusion. As a result, with the serologic aid of Dr. R. W. Koucky, a large pool of antibody titer findings has been formed. This pool of findings has been kept continously open by Dr. Koucky to the inspection of all. Throughout, he has been deserving of the thanks of all involved in giving unstintingly of his serologic experience and advice. The interpretations of the data are those of an obstetrician and, if incorrect, must not be attributed to him.

Conclusions

Genetics decrees that the relationship between fetus and mother is a toxin-antitoxin relationship if the fetus contains toxic antigens not possessed by the mother.

Three of the now known and lettered antigens, namely the A, B, and Rh antigens are, by adequate definition, toxins, when functioning under the above conditions.

In nature, their functioning as agglutinogens marks the beginning of demise and disintegration of the fetal red cells under antitoxin attacks as obtains with bacteria. The liberation of the toxins from the red cells merely augments the strength of the toxins already in the serum.

The symptoms, signs and pathological findings in pregnancy toxemia are caused by one or more of the three blood substances: A, B, and Rh. There may be others, yet unknown.

In erythroblastosis fetalis we are witnessing the destructive action of the antitoxin on the cells from which the toxin arose.

One of the functions of the placenta is to act as a first line of defense in the toxin-antitoxin battle. Due to its anatomic structure, this line of defense is at times broken down, with consequent spilling of fetal serum and red blood cells into the maternal circulation. It would seem that placental infarcts mark the points of leakage, due to the functional capacity of the agglutinin in the antitoxin working upon the agglutinogen in the fetal red blood cells.

THE BEDSIDE DIAGNOSIS OF LIVER DISEASE

EDMUND B. FLINK, M.D.

Assistant Professor of Medicine
University of Minnesota Medical School
Minneapolis, Minnesota

IN dealing with patients with obvious liver disease (jaundice or hepatomegaly or similar evidences) the diagnosis can frequently be made at the bedside by the simple expedient of a careful history and physical examination. Furthermore, it is fair to say that a careful history of the illness and a physical examination of the patient must precede all other procedures in the diagnosis of liver disease.

The history should include an orderly inventory of the following facts with complete details of each positive finding. The character, location, radiation and duration of pain and time relationship to meals, relationship to fatty and fried foods, association with jaundice, and association with nausea and vomiting adequately describe one of the most important symptoms. The absence of pain is important, too. The onset, duration, and fluctuation of jaundice and its association with pruritus, relation to the color of the urine and feces, to pain, to the use of toxic drugs such as sulfanilamide, cincophen, dinitrophenol and arsenicals, or to exposure to carbon tetrachloride and trinitrotoluene, characterize the other one of the most important items of the history. The occurrence of the prodromal symptoms anorexia, fever, chills, nausea and vomiting and occurrence of an epidemic of jaundice in the neighborhood are of particular significance in the diagnosis of epidemic hepatitis. Previous plasma or blood transfusions or the use of homologous serum may antedate the onset of hepatitis by thirty to ninety days. A family history of intermittent or persistent jaundice and anemia in many members signifies familial hemolytic anemia in all probability. The amount and duration of the use of alcoholic beverages is important in ascertaining the etiology of hepatic cirrhosis. Intimately related to the alcohol consumption is the question of adequacy of the diet in the past during alcoholic debauches. The occurrence in the recent or remote past of such illnesses as malaria, typhoid, brucellosis, syphilis (and its treatment with arsenicals), amebiasis, and chronic ulcerative colitis may furnish a clue to the etiology of liver disease or of gallstones. As a cause of upper gastro-intestinal hemorrhage bleeding from esophageal varices is common, second in importance only to peptic ulcer. Edema, ascites, weight loss, anorexia and asthenia are common symptoms in advanced cirrhosis.

There are certain features of the physical examination which are of crucial importance in the diagnosis. The appearance of the jaundice and its intensity, the presence of absence of a green tint (or biliverdin icterus), and evidence of pruritus are easily detected by careful inspection of the whole body in good natural light. Considerable jaundice may be overlooked by examination in poor artificial light. The presence of spider nevi over the upper half of the body may be an important clue in the diagnosis of cirrhosis. Spider nevi are small arteriolar hemangiomata with a central pulsating punctum and radial striations extending a few millimeters to as much as a centimeter from the center giving the appearance of a spider. Sometimes the patient is aware of their presence and can tell when each one has appeared, but more often he is ignorant of their presence. They are easily overlooked unless a special search is made for them. Their presence does not establish the diagnosis, but characteristic nevi are presumptive evidence of hepatic cirrhosis. They may occur in normal individuals, during normal pregnancy or diseases of non-hepatic origin. They must be differentiated from the bright red telangiectases without radiations occurring normally over the trunk of adults. Palmar erythema commonly occurs in patients with cirrhosis and nutritional disorders.

The breath of a patient with jaundice should be carefully noted each day. When liver necrosis occurs, there is a characteristic odor termed fetor hepatis or amine odor. It is an aromatic, pungent, sweet odor, which may become so prominent that it pervades the whole room; on the other hand it may be detected only by smelling of the breath directly.

If a patient with jaundice from hepatitis is fasted for a relatively short period of time, hypo-

---

glycemic episodes may occur with any or all of the symptomatology of an insulin reaction. Stupor, delirium or actual coma may develop independently of hypoglycemia and are of very grave prognostic significance, for there are few patients who recover after becoming comatose. The abdominal examination offers certain helpful and occasionally absolutely diagnostic signs. The presence of ascites is not difficult to elicit when a moderately large amount of fluid is present in the abdominal cavity. The most sensitive index of free fluid is the presence of shifting dullness, i.e. with dullness to percussion over the dependent parts of the abdomen regardless of position. When enough fluid is present, it is possible to identify solid masses by the maneuver of "dipping"; a sudden but, nevertheless, gentle dipping with the fingers of one hand at the level of dullness will give a sensation of splashing fluid against a solid mass whenever one is present. The phenomenon is evidence for free fluid as well as for a tumor mass. Of course, there are many causes for ascites, but one of the most important causes is liver disease and especially cirrhosis. Ovarian cystomas of large size frequently cause confusion with large amounts of free fluid in the peritoneal cavity. The absence of shifting dullness and the presence of flatness in the midline of the abdomen with the patient in the supine position are the most important differentiating features of ovarian cystomas. Pelvic examination may fail to reveal any definite connection of a mass to the uterine adnexae. The rectum must be examined in every patient and it is often possible to detect a "rectal shelf" in patients with carcinomatosis of the peritoneum causing ascites.

Palpation of the liver is easy when it is moderately or markedly enlarged. Careful notation of its consistence, surface, edge, and extent below the costal margin in the mid-clavicular line are important. The edge of a normal liver can often be palpated on deep inspiration. The daily observation of the size of the liver including its upper margin of dullness anteriorly is important in hepatitis. If the liver suddenly decreases in size and continues to do so, and if there is a fetor hepatis and disturbed sensorium, the prognosis is very poor.

The presence of signs of localized peritonitis in the right upper quadrant in association with fever, chills, nausea and vomiting, fatty food intolerance and colicky pains is practically diagnostic of acute inflammatory gall-bladder disease or an acute recurrence of chronic gall-bladder disease. In such patients jaundice usually is evidence of common duct obstruction from stone. An inflammatory mass may be palpated below the margin of the liver in many instances especially when the acute disease is subsiding. Generalized peritonitis may develop as the result of rupture of an acutely inflamed gall bladder with stones.

One of the most neglected and the least appreciated findings in liver disease is splenomegaly. In cirrhosis, acute hepatitis and acute liver necrosis, the spleen frequently is enlarged enough to be palpable. The presence of splenomegaly in a jaundiced patient definitely points toward primary liver disease as a cause of jaundice. Of course it may be enlarged in biliary cirrhosis, may be present as an independent finding in an unrelated but concomittant disease, or the patient may have a familial hemolytic jaundice or anemia. Suffice it to say that the presence of a palpable spleen is evidence of an abnormal state, and one must think strongly of liver disease.

One sign, when present, has more diagnostic importance than any other. In a jaundiced individual the presence of a palpable, non-tender, smooth gall bladder is practically pathognomonic of carcinomatous obstruction of the common bile duct anywhere from the entrance of the cystic duct to the ampulla of Vater. When a gallstone obstructs the common bile duct, the gall bladder seldom is palpable because of previous inflammation with thickening of the gall-bladder wall which prevents distention. A previously normal gall bladder can distend readily. Courvoisier recognized these facts many years ago. Failure to palpate the gall bladder does not exclude carcinomatous obstruction. A distended gall bladder in a non-jaundiced individual is known as hydrops of the gall bladder and must not be confused with the occurrence in a jaundiced individual. This is due to cystic duct obstruction by a gallstone usually. The gall bladder may be palpated when it has a very large stone or many large stones in the fundus. Carcinoma of the fundus of the gall bladder causes an irregular hard mass. Inflammatory masses are usually tender.

A differential diagnosis of liver diseases and diseases of the extra-hepatic biliary tract is possible from the observations made at the bedside and often a definite diagnosis can be made.

Jaundice of the retention type occurs in two diseases. In constitutional hepatic dysfunction there is a very mild jaundice. Usually other members of the family also have mild jaundice. No systemic symptoms and no anemia occur. The spleen is not palpable. In familial hemolytic anemia or icterus the patients are mildly or severely anemic from birth. Jaundice fluctuates greatly. The spleen is always enlarged and usually palpable. One can often get the history of exacerbations of symptoms with chills and fever often called hemolytic crises. Gallstones form in a large number of these patients so it is entirely possible to have the history of typical gallstone colic superimposed upon or even overshadowing the primary complaints thus making the differential diagnosis more complicated. The acquired type of hemolytic anemia with jaundice may be secondary to other diseases such as blood dyscrasias or liver disease, but may also be primary. The spleen is palpable and the anemia is evident, but there is no family history of similar illness except by rare coincidence, and the illness does not date back to infancy or early childhood.

The largest group of jaundiced patients have a regurgitation type of jaundice and it is of utmost importance to establish whether or not there is extra hepatic biliary obstruction or parenchymal liver disease. The urine is beer-brown in color and the stools light to acholic. The liver is enlarged but there is no splenomegaly in simple extrahepatic obstruction of the bile ducts unless the jaundice has persisted for a long time (many months to years). It is necessary to differentiate between cancerous obstruction and calculous obstruction in the group of cases with extrahepatic obstruction.

The commonest type of jaundice (except during an epidemic of hepatitis) is that due to gallstone obstruction of the common bile duct. Characteristically the jaundice fluctuates in intensity, is abrupt in onset and is less intense than in carcinomatous obstruction. The stools may or may not be acholic. Colicky pain which is severe and radiates from the right upper quadrant of the abdomen to the region of the right scapula and interscapular region is present at some time during the early course of illness and usually before the onset of jaundice. Nausea and vomiting frequently accompany bouts of pain. The jaundice deepens perceptibly when there has been an attack of pain unless the stone was passed into the duodenum or shifted in position. The past history of definite intolerance for fatty and fried food, cabbages, onions and especially the history that food actually induces typical gallstone colics are very helpful. Obstruction due to gallstones may be "silent" in so far as an association with pain is concerned. Observation of fluctuation in the intensity of jaundice, in the color of the stools, episodes of chills and fever all suggest the presence of gallstones. It may be impossible to differentiate the "silent" type of gallstone obstruction from acute hepatitis.

Cancerous obstruction is characteristically painless, but there are a number of patients who have vague deep-seated epigastric pain or even pain suggesting gallstone colic. The jaundice is intense, persistent, associated with pruritus and usually abrupt in onset. Usually there are no chills, fever or vomiting. The gall bladder is frequently palpable below the liver margin and is not tender. This finding is of the greatest importance, for it is pathognomonic of cancerous obstruction of the extrahepatic biliary tract in the jaundiced patient. Carcinoma of the gall bladder and bile ducts usually occurs in patients with gallstones too so any or all of the symptoms of chronic cholelithiasis may be present in the past history or the present illness. Carcinoma of the gall bladder may cause a great deal of pain but causes jaundice only in the cases where it invades the common bile duct.

Rarer forms of obstructive jaundice are due to lymph-node enlargement at the porta hepatis causing compression of the hepatic or common bile ducts. Hodgkins disease, lymphatic leukemia, lymphosarcoma or carcinomatous metastases may be the primary disturbance. Recognition of lymphoblastomata is aided by finding generalized lymph-node enlargement and moderate to very marked splenic enlargement.

Stricture of the common bile duct is a serious complication of cholecystectomy in which the duct was inadvertently ligated, cut, or injured. The history usually reveals that jaundice began shortly after operation and persisted, that a large amount of bile suddenly appeared at the wound as if from an abscess which ruptured, bile continued to drain indefinitely from the wound, and jaundice appeared or deepened as soon as the bile fistula closed. Strictures frequently are not treated immediately, so biliary cirrhosis with hepatomegaly and splenomegaly develop.

Regurgitation jaundice of hepatic origin is frequently encountered. The onset of jaundice immediately after exposure to toxic chemicals or drugs such as carbon tetrachloride, cincophen, dinitrophenol, arsenicals, sulfanilamide, benzene, etc. suggest the specific chemical as the etiological agent. The history of exposure to patients with epidemic hepatitis, transfusion with human blood or blood derivatives, the use of homologous sera of any kind in the recent past directs one's attention to acute hepatitis which probably is due to a filterable virus or viruses. The history of prodromata including fever, severe anorexia, nausea and vomiting, malaise, and bowel disturbances before the onset of jaundice is very suggestive evidence in favor of acute hepatitis. There are authentic cases of acute hepatitis without jaundice and these are very difficult or impossible to recognize unless an epidemic is occurring. The spleen is palpable in about one-half of the cases and undoubtedly the percentage is higher when daily examinations are made. The size of the liver should be noted on initial examination and checked frequently during the course of illness. Observation of the breath for a fetor hepatis and observation of the sensorium have been emphasized above. Daily observations of the feces for the appearance of bile-pigment is important for the recognition of the recession of jaundice. Ascites may be present in the more severely ill patients.

Recognition of hepatic cirrhosis is dependent on the finding of some of the characteristic features such as a firm, finely nodular liver, enlarged spleen, spider nevi, ascites, evidences of collateral circulation on the abdominal wall and evidence of malnutrition and jaundice. Probably not more than half of all of the patients are jaundiced and any of the above-mentioned features may be missing. The skin is soft and the axillary hair is often sparse. When the skin is deeply pigmented in a male who is also diabetic, one should suspect hemachromatosis or pigment cirrhosis.

The liver may be enlarged as a secondary manifestation of other diseases. Congestive heart failure causes chronic passive congestion of the liver. The liver frequently is tender to palpation, and not infrequently the patient may have pains in the right upper quadrant of the abdomen as a result of the congestion. Metastases to the liver may cause massive enlargement of the liver. One can recognize metastatic nodules in the liver with reasonable certainty if one can palpate a depressed area in the center of the nodule. The liver often is tender when it is filled with metastases. Recognition of symptomatology and physical characteristics of the primary carcinoma is very important. There are many other diseases which may affect the liver secondarily, but these will not be discussed separately.

Summary

The importance of the clinical examination of the patient with evident or with suspected liver disease cannot be overemphasized. There is often a tendency to turn quickly to laboratory aids without adequate clinical examination. However, the so-called liver function tests may help and may confirm a clinical diagnosis or indicate the need for more prolonged observation and study of a case. Admittedly there are times when the clinical picture is so complex that an exact anatomic diagnosis of the liver disease can be made only by some type of surgical procedure. Careful interpretation of the details of the history and of the physical examination will often, probably in the majority of cases, direct the doctor to the correct diagnosis.

WHY DO AIR TRAVELERS CHEW GUM?

People making their first trip by air are surprised to have the hostess offer them gum to chew as the plane lands. The reason for the gift of gum, says the Sonotone research laboratories, is that the working of the jaws in chewing tends to keep the air pressure equalized on both sides of the ear drum. Chewing action opens the throat end of the Eustachian tube, which is an air duct leading to the middle ear. In landing, an airplane moves from low to high atmospheric pressure, a situation which would cause discomfort if the increased pressure was exerted only on the outer side of the ear drum.

KERION: A REVIEW

CARL W. LAYMON, M.D.
Minneapolis, Minnesota

IN modern medical writing the term kerion is used to designate an acute, highly inflammatory, carbunculoid type of fungous infection which predominantly involves the scalp and bearded region. The word is an extremely old one in medical nomenclature, the ancient Greeks having used it to denote deep, infiltrative, cutaneous inflammations. Kerion is not unusual in this part of the Midwest because a fair proportion of the population is engaged in farming or dairying, occupations which necessitate close contact with animals which are subject to fungous infections due to species which cause this type of reaction.

Kerion can be produced by several species of fungi. Lewis and Hopper[3] reported this form of infection due to Trichophyton gypseum, Microsporum lanosum, M. audouini, M. fulvum; T. crateriforme and T. niveum. The great majority of cases are produced by species of fungi which are highly pathogenic to animals (zoophilic fungi of Wise and Sulzberger[9]), especially T. gypseum. It is extremely rare that the so-called human pathogens (anthropophilic fungi of Wise and Sulzberger) evoke such a reaction.

Clinical Features

At the beginning kerion rarely presents the granulomatous tumefactions which are so characteristic of the disease at the peak of its intensity. It usually starts as an ordinary patch of squamous or vesicosquamous ringworm on a hairy area or which has spread to a hairy area from a neighboring portion of the glabrous skin. In some instances the early lesion resembles an ordinary, small furuncle. Frequently there is but one lesion and rarely more than a few. Within a short time the plaques become larger and more inflamed and the surface becomes covered with impetiginous crusts. After a few days, or at the most two or three weeks, follicular pustules, either few or in large numbers, predominate the picture. This pustular, follicular infection spreads to the perifollicular tissues and through confluence of the adjoining follicular infiltrations, the entire lesion becomes a boggy edematous mass. In this fully developed stage the lesion is a rather sharply demarcated, sloping bordered, macaroon-like, spherical tumor of red or livid color which, for a time, is firm and later mushy due to coalescence of the follicular abscesses. At this point the surface is oozing and the follicular pustules, when broken, emit sanguinous pus. The odor is repulsive. The individual round lesions increase in size but rarely grow larger than 6 or 7 cm. in diameter. They are usually raised from 0.5 to 1 cm. above the plane of the surrounding skin. The first lesion is usually the largest and these which appear later rarely become as large, although sometimes there may be 6 or 8 kerions on the scalp or bearded region which are of almost equal dimensions. The skin between the lesions is usually normal or presents only a scattering of follicular pustules which occasionally coalesce to form small nodular foci. There is considerable variation in the intensity of the inflammation in different cases.

After the inflammation has reached its height the pustules evacuate their contents and the affected hairs are expelled. At this stage the surface becomes smooth and hairless and the epidermis thin and tense. Extensive erosions and even ulcerations frequently develop and the gaping follicular openings give the lesions a "worm-hole" appearance.

Early in the course of kerion the hairs are unbroken and appear normal. Stubby hairs, which are so frequently noted in infections due to anthropophilic fungi, are rarely seen in kerion. Later, when the phase of purulent folliculitis is fully developed, the hairs can be extracted easily without breaking them. Apparently healthy hairs, situated between the grossly diseased ones, can sometimes be pulled out without difficulty, the root being atrophic as a result of the neighboring inflammation. Even in the final stages, after expulsion of most of the hairs, a few tufts of healthy hair may remain.

The average duration of kerion is six or eight weeks, although severe cases may last for three months. There is a constant tendency toward spontaneous healing. The hair almost always regrows and there is an eventual return to complete

Kerion of the Beard in a Farmer.

normalcy, although permanent baldness may occur rarely.

Besides the aforementioned local changes, systematic symptoms are commonly noted as a result of absorption of substances into the lymphatics and blood stream. In kerion of the scalp a retro-auricular, occipital and cervical adenitis is an almost constant finding and lymph nodes even farther removed from the primary focus may be enlarged. The nodes are at first firm and tender; later there may be softening and rupture to the surface. Fatigue, malaise, and cephalgia have been observed frequently. The fever may be high in cases of extensive kerion. Miescher[5] reported cachexia in extremely severe cases. The blood usually shows a polymorphonuclear leukocytosis.

Kerion of the beard, or sycosis parasitaria, is analagous to the disease as it occurs on the scalp. Beginning as superficial, vesicular, discoid or ringed foci, a pustular folliculitis soon develops and the entire lesion becomes edematous and raised above the surrounding skin. As a rule there are only a few foci; sometimes only one surrounded by small abortive lesions. Rarely, new superficial vesicular foci develop side by side with the granulomatous masses and nodules. As on the scalp the skin between the lesions is usually normal. The chin and sides of the face are the most common sites of involvement; rarely the upper lip is affected. The general symptoms and course parallel those of kerion of the scalp.

Kerionic lesions occasionally occur on areas other than the scalp and bearded region presumably due to infection of lanugo hairs by ectothrix trichophytons. Such lesions have been noted on the dorsums of the hands, forearms, sides of the neck, buttocks, inguinal region and external ear. The term "agminated folliculitis" has been used to designate this affection.

Granduloma trichophyticum should also be mentioned in relationship to kerion. It is a form of deep, infiltrative trichophytosis first described by Majocchi[4] and discussed chiefly in the Italian literature. It is characterized by round, smooth, indolent, bean- to nut-sized nodules which are tender on pressure, and usually light red in color. There is a tendency toward grouping. Early in the course of the disease the nodules have an elastic consistency but later become soft and almost fluctuant. In some cases, however, they become hard and keloidlike. There are no signs of suppurative folliculitis or abscess formation as in kerion, a point which was stressed by Majocchi and subsequent writers. The softening which occurs in the lesions represents a secondary necrobiotic change in the granulation tissue similar to that which occurs in gumma. On pressure a serosanguineous material rather than pus can be expressed. Impetiginous changes and pustules at the follicular orifices occasionally occur late in the disease but are regarded as a secondary infection by pyogenic cocci.

The nodules don't develop primarily but become superimposed on a focus of ordinary ringworm almost exclusively produced by anthropophilic fungi. The lesions are usually located on the scalps of children from six to twelve years of age or on the bearded regions in adults. Rarely they develop from squamous lesions of the glabrous skin.

The course of granuloma trichophyticum is extremely torpid, the disease usually lasting several months. In time the granulation tissue resorbs or softens, and sometimes degenerated material is discharged on the surface. The skin may return to normal or become somewhat atrophic.

There has been considerable discussion concerning the mode of entry of fungi which are found in the granulation tissue in the cutis. Although some authors have stated that the fungi penetrate from the surface directly into the cutis, the concensus is that the follicles represent the point of entry since, in the course of the affection, the diseased hairs and follicles become degenerated permitting the resorption of fungus elements into the cutis. Sabouraud thought that there was no good proof that there was any active emigration of fungi from the surface to the cutis. Disintegration of the follicle, whether as a result of purulent inflammation or degeneration, thus plays the principal role in the development of granuloma trichophyticum. Majocchi and Mazza tried to introduce fungi directly into the cutis in an effort to produce this type of the disease experimentally, but the results were practically negative. Following intracutaneous implantation of fungi in humans and dogs, nodules or abscesses rapidly formed followed by expulsion of the fungi. Similar attempts in cock's combs produced infiltrated plaques and nodules after 3 to 4 weeks which involuted slowly and showed tuberculoid structure histopathologically. Majocchi, however, did not believe that the lesions were analogous to those in the human as the course was much more rapid and the tendency to heal much greater.

So-called chronic kerion represents a slowly progressive gummoid change of the contents of ordinary kerion and is always preceded by an acute stage with pustular folliculitis.

In those cases of granuloma trichophyticum in which trichophytin tests were done, the reactions were weakly positive in contrast to the strongly positive reactions which characterize kerions.

As far as other diseases are concerned the differential diagnosis of kerion is usually not difficult. The prominent feature of pustular folliculitis is against other granulomas such as syphilis, tuberculosis, actinomycosis, blastomycosis and mycosis fungoides. The relatively sharp demarcation of the lesions aids in the differentiation from pyoderma, though in its early stages kerion may resemble impetigo. In the former, however, tiny blisters and pustules may be seen as the border while the individual lesion in impetigo is a bulla which spreads peripherally.

On the face there may be confusion with staphylococcic sycosis in the early phases of kerion. One of the chief characteristics of the latter, however, is the agmination of small lesions to four larger nodules, a feature not seen in ordinary sycosis. The presence of round and annular vesicular foci characterizes the initial stages of kerion but not coccygenic sycosis. The latter affects the upper lip with great frequency while kerion almost never occurs in that location.

Chancre of the face is not apt to be confused with kerion since there are no follicular pustules in the former.

Demonstration of the causative fungi in wet preparations and cultures affords a definite proof in the final diagnosis of kerion.

Examination of Hairs and Pus—Cultures—Inoculations

Sabouraud stated that it is a curious but certain fact that the examination of pus from kerion almost never shows recognizable fungi, yet cultures from the pus are usually positive and are regarded as the easiest and surest proof of the nature of the disease. This is explained by the fact that the dissociated fungous elements are so easily confused with cellular debris. In fully developed kerion it is almost impossible to demonstrate fungi along the hairs in potassium hydroxide preparations although such examinations are positive at the very beginning of the lesion. As previously mentioned the vast majority of cases of kerion are due to Trichophyton gypseum. The growth of the organism is largely on the outside of the infected hair which becomes covered by a mantle of mycelial elements and spores. The latter are 2 to 4 mm. in size and, in wet preparations of potassium hydroxide, appear to have the same mosaic arrangement which characterizes the microsporums. If the slide is pressed a little bit, however, it can be seen that the spores of T. gypseum are arranged in chains, a feature never seen in microsporum infections.

Inoculations into the skin of both humans and animals is not difficult. Sabouraud spoke highly of Rivalier's procedure in which a paste containing a mixture of honey and culture powder is applied to a hairy part of the skin. The inoculation is usually positive by the seventh day. The hair of the monkey illustrates the microscopic features of T. gypseum in hair more beautifully and schematically than human hair. Sabouraud stated that primary cultures should be used for inoculation, since in later cultures the parasitism is changed and sporulation is lost.

In animals the infection is less intense and suppurative than in man. Discharge from the lesions resembles large drops of glue which exudes from between the hairs and mats them down.

Histopathologic Features

The histopathologic findings in kerion vary considerably in extent and intensity. In the beginning inflammatory changes in the epidermis are noteworthy, and the tendency to follicular localization is evident early in the course of the disease. Superficial epidermal spaces filled with leukocytes may be seen and there is a perifollicular infiltrate made up of lymphocytes, plasma cells and polymorphonuclear leukocytes. By means of the gram stain mycelial filaments may be demonstrated in the horny layer of the follicles and around the hairs. As the disease progresses the inflammation spreads toward the hair root although the latter is the last part of the hair to become affected and may be entirely spared. The luxuriant growth of fungi about the hair shafts has, in Miescher's opinion, much to do with the high degree of allergy in kerion. The tissue reaction is so exudative that small abscesses may develop in the middle or upper portions of the follicle. The infected hair finally loosens and falls out, leaving only the root. The sebaceous glands associated with the follicle are also involved early and after a stage of leukocytic invasion the entire structure disintegrates.

The follicle walls become edematous, vacuolated and permeated by leukocytes. The degenerated cells stain poorly. Lymphocytes, plasma cells, and eosinophils also make up part of the infiltrate along with large macrophages, large nucleated fibroblasts and epithelioid cells. The perifollicular vessels are dilated and filled with leukocytes. After complete degeneration of the follicle wall spherical abscesses may be seen in the cutis, some of which contain bits of disintegrated hair and fungi. Degenerated filaments and spores may also be seen lying free between the leukocytes. No other micro-organisms are in evidence and cultures of pus show single colonies of staphylococci only exceptionally. The inflammatory and degenerative changes in kerion seem out of all proportion to the number of fungi seen in the tissues.

In severe cases the abscesses penetrate to the surface, usually through the follicular orifices and only rarely through degenerated intrafollicular portions of the skin. In less severe cases the abscesses are gradually absorbed. Late in the course of kerion giant cells, both the foreign body and Langhans types, may be seen along with epithelioid cells and fibroblasts. Portions of the degenerated follicle remain as irregular epithelial masses. Another feature which has been observed is the formation of pseudoepitheliomatous changes of such degree that differentiation from true epithelioma may be difficult. In these cases irregular karyokinesis and pearl formation may even be present, adding to the confusion. Fully developed kerion presents a variegated and complicated picture. Not all adjoining follicles are affected and those which are involved become so at different stages of the disease. Some follicles remain completely intact throughout the entire course.

Because of the degenerative changes in the follicles and the formation of granulomatous infiltrations as deep as the subcutaneous blood vessels, the entire architecture of the cutis is changed. The elastic and collagenous fibres diminish to mere remnants. The sweat glands may be seen unchanged in the center of a granulomatous mass. Usually epithelial sprouts may be seen in the upper part of the follicles which later take part in the process of regeneration. These sprouts, along with follicles which escape the inflammation, explain why permanent baldness is rare.

In granuloma trichophyticum the tuberculoid structure of the infiltrate is outstanding as compared to the acute pustular folliculitis which predominates the picture of kerion. In the former, the middle and deep portions of the cutis are involved by such nodular infiltrations. The infiltrate is perifollicular and the follicles are often cystic and degenerated to the point of being unrecognizable. Fungus containing fragments of hairs lie free in the granulation tissue. Fungi may also be seen between the cells or enclosed in giant cells. In the unusual fibroid form of granuloma trichopyticum fibrous masses are present in the cutis. Suppurative changes in this form of fungus infection are much less noticeable than in kerion.

Allergy in Kerion

Bloch[1] studied the biologic and allergic phenomena in fungous infections extensively and he and Jadassohn and their followers contributed much of the original work in this field, much as Koch and his school did in tuberculosis. Although many species of animals have been used in experimental work on pathogenic fungi, the guinea pig has remained the principal animal and Achorion quinkeanum the principle fungus in studies concerning diseases produced by Hyphomycetes. Sulzberger[7] stated one strain of A. quinkeanum has been used in Zurich for over 30 years and has regularly produced uniform experimental results.

Primary infections in the guinea pig run their course in three or four weeks with the peak of intensity about the twelfth day. In reinoculations the response is accelerated, being most intense within six days and completely healed in ten or twelve days.

Similar experiments in man strongly resemble those in the guinea pig as far as the difference between first inoculations and reinoculations are concerned, except that in man the course of events is less constant and regular. Differences in individuals and variations in the response at various inoculation sites are greater in man. Variations in the response to various strains of fungi are also more noticeable. In general, the duration of the infection is much longer (two or three months in first inoculations of A. quinkeanum), and the periods of peak intensity and resolution are not so sharply bordered. The length of the inoculation period is also more fluctuant. In man the entire course of events more closely approaches that which takes place in the guinea pig when experimental inoculations are made with fungi of low virulence. In man, the more virulent the strain used for inoculation, the greater is the analogy to the infection in the pig.

In reinoculations in many with zoophilic fungi, whether the first infection was spontaneous or artificial, the reaction is accelerated and the course of the infection is abortive or shortened, influenced by the allergy of the entire skin produced by the first inoculation. This allergy is not type-specific and persists after the primary infection has healed. The degree of allergy depends on the type of fungus, the mode of inoculation, the individual and other unknown factors. Accordingly, the reaction to reinoculations varies from those which closely simulate the first inoculating to accelerated abortive infections in which fungi can be demonstrated to, finally, almost complete allergic reactions in which no fungi can be found. Other factors which influence the degree of allergy and the fate of reinoculations are the depth, extent and number of primary foci, the number of preceding inoculations, and the distance of the reinoculation site from the primary focus. There are undoubtedly other factors too, such as the individual capacity to react to a pathogenic organism and the ability of certain fungi to elaborate allergizing substances. Experimental reinoculations in patients with kerion have been performed by various workers and the results have followed the general rules previously outlined.

In infections in man produced by anthropophilic organisms the degree of skin sensitivity is not high. In kerion, however, and in other infections produced by zoophilic fungi the degree of sensitivity to trichophytin is high. There are exceptions to these general rules, however, which defy explanation.

In kerion, "id" eruptions are not uncommon because of the high degree of sensitivity. In this type of infection especially, the sequence of exposure, primary infection, development of allergy, development of primary lesions and the eruption of the "id" is often clearly apparent. In trichophytids almost every form of allergic reaction of the skin may be represented, although deep granulomatous and necrotic processes seen commonly in tuberculids and syphilids are rare among "ids" due to fungi.

Treatment of Kerion

In discussing the therapy of kerion two points should be brought out: (1) There is an outspoken tendency toward spontaneous healing and (2) the treatment is not as routinized as in infections due to anthropophilic organisms such as tinea capitis due to M. audouini. Many therapeutic methods have been described in the literature and it is not easy to evaluate them because the favorable end result is inevitable on biologic grounds alone.

The various therapeutic measures may be discussed under the following headings:

A. Local Agents Not Specifically Antiparasitic.—These include soothing, cleansing and softening agents such as moist compresses, moist or dry heat, ultraviolet radiation, incision of small abscesses and currettage of masses of granulation tissue. Dr. Charles Freeman[2] believes that the judicious use of solid carbon dioxide shortens the course of kerion. In most cases mild, moist compresses which soften and remove crusts and facilitate drainage, constitute the best treatment of the disease.

B. Epilation (Manual or By Means of X-rays).—Since the severity of the inflammation in kerion results in expulsion of the diseased hairs epilation by means of x-rays is rarely, if ever, indicated. Manual epilation of infected hairs, along with the removal of crusts, is helpful.

C. Strong Antiparasitic Remedies.—The use of medications containing high percentages of resorcin, sulfur, chrysarobin, mercurials and salicylic acid is rarely necessary. The use of 20 per cent salicylic acid ointment has favorably impressed Ormsby.[6] The internal use of iodine is unnecessary in kerion.

D. Non-specific Stimulation of Immunobiologic Defense Mechanisms.—Intramuscular injections of turpentine in olive oil, injections of milk and the use of intravenous typhoid vaccine have been used by many in the treatment of kerion. The concensus is that such methods are of slight value.

E. Trichophytin Desensitization.—Oppenheim is firmly convinced that trichophytin desensitization is valuable in kerion and other forms of fungous infection. Miescher believed such treatment was helpful in kerion, but of no value in non-inflammatory types of mycosis. In the experience of most observers such treatment has been unnecessary and since untoward local and systemic reactions can result it seems contraindicated in a disease which heals spontaneously.

POSTMORTEM EXAMINATIONS AND THE JEWISH LAW

Because of the undesirability of some resistances against postmortem examination that appear among the relatives of Jewish patients who die, Dr. I. M. Rabinowitch, special lecturer in medical jurisprudence at McGill University, Montreal, recently investigated the laws with regard to postmortem examination contained in the Bible and in the Talmud. He points out that the attitudes of non-Jewish people of the same period toward postmortem examinations were much the same as those of the Jewish people. Arguments in favor of prohibiting postmortem examinations are based on four authentic instances in which a requested postmortem examination was prohibited by a celebrated rabbi. However, Rabinowitch points out that permission was refused in each instance because of the argument that the postmortem examination would not be of any value either in clearing the cause of death or of any benefit to the living. The thorough search which Rabinowitch has made convinces him that nowhere in the Bible, in the Talmudic, in the post-Talmudic or in the later Rabbinical writings is there any evidence that postmortem examinations are prohibited by Jewish law. Indeed, such prohibition would be inconsistent with the fundamental directing principle in Judaism—"The Laws were given that man shall live by them, not that they shall die by them."—*J.A.M.A.*, 130:151, (Jan. 19) 1946.

URETERAL OBSTRUCTION CAUSED BY ANEURYSM OF THE ILIAC ARTERY

HUGH F. RIVES, M.D. and EDWARD N. COOK, M.D.
Rochester, Minnesota

LAZARUS and Marks[1] have described the urinary symptoms associated with aneurysm of the abdominal aorta. They pointed out that the most frequent causes are arteriosclerosis and syphilis. The most common urographic finding in their cases was renal or ureteral displacement, and they stressed the diagnostic value of lateral pyeloroentgenogram.

We wish to report a unique and unusual case. It is the only such case seen at the Mayo Clinic. A review of the literature, although not completely comprehensive, has not revealed a similar case.

Report of Case

A man, fifty-eight years of age, was first seen at the clinic February 21, 1944. He had been perfectly well until two and a half months previously, when he had had generalized aching, malaise, loss of appetite and a temperature of 102° F. The fever had lasted several weeks and the patient had been treated symptomatically. One month after his illness, severe pain had occurred in the right groin and had extended to the right testis and right renal region posteriorly. The pain had been accompanied by hematuria, pyuria and urinary frequency. Treatment with sulfanilamide for one week had produced some improvement but very severe pain subsequently had occurred in his right groin and right hip. The pain in the hip had seemed to extend posteriorly to the midline of the lower part of the back. Urologic investigation was said to have disclosed bilateral pyelonephritis and two small stones in the left kidney. Urinary culture had revealed Salmonella aertrycke. Treatment with sulfanilamide had been continued and the fever and pain had subsided gradually in about ten days. During the next three weeks the patient had had intermittent fever and pain in the right groin. At the end of this period, he came to the clinic. The patient was well developed and well nourished but appeared moderately ill. The lungs and heart were normal. The blood pressure was 104 mm. of mercury systolic and 54 mm. diastolic. The pulse rate was 88 and his temperature was 101° F. The abdomen was slightly distended and there was some tenderness in the suprapubic region. Rectal examination revealed a questionable nodule in the lower pole of the right lobe of the prostate gland. It was felt that the patient possibly had carcinoma of the prostate.

Microscopic examination of the urine revealed hematuria, grade 1 (on the basis of 1 to 4), and pyuria, grade 2 (35 cells in each microscopic field viewed under the high-power objective). Urinary culture disclosed Salmonella. The value for the hemoglobin was 9.1 gm. per 100 c.c. of blood. The erythrocytes numbered 3,580,000, and the leukocytes numbered 6,600 per cubic centimeter of blood respectively. Flocculation tests for syphilis were negative. The value for the blood urea was 26 mg. per 100 c.c.; the value for the alkaline serum phosphatase was 7.0 units (King-Armstrong) per 100 c.c., and the value for the acid serum phosphatase was 1.0 unit per 100 c.c. The sedimentation rate of the erythrocytes was 93 mm. in one hour (Westergren). A roentgenogram of the thorax revealed torsion of the aorta. Anterior, posterior and lateral roentgenograms of the lumbar vertebrae did not reveal any abnormality. An excretory urogram disclosed delayed excretion on the right side and dilatation of the renal pelvis and calices and upper part of the ureter. The cause of the obstruction was not evident. Urography did not disclose any abnormality of the left kidney except a small cluster of shadows (Fig. 1). The cause of these shadows could not be determined. At this stage of the examination, it was felt that the patient probably had a carcinoma of the prostate which had caused obstruction of the right ureter. On February 23, 1944, cystoscopy revealed a trilobar prostatic enlargement, faint trabeculation of the bladder and erosion of the right ureteral orifice. A No. 5 ureteral catheter could be passed easily up the right ureter although it seemed to fit snugly as it was being passed through the portion of the ureter corresponding to the wall of the bladder. A catheter could be passed easily up the left ureter. Rectal examination was repeated and the prostate was thought to be the site of a malignant lesion. Repeated attempts to obtain a right pyelogram were unsuccessful. A left pyelogram did not disclose any abnormality.

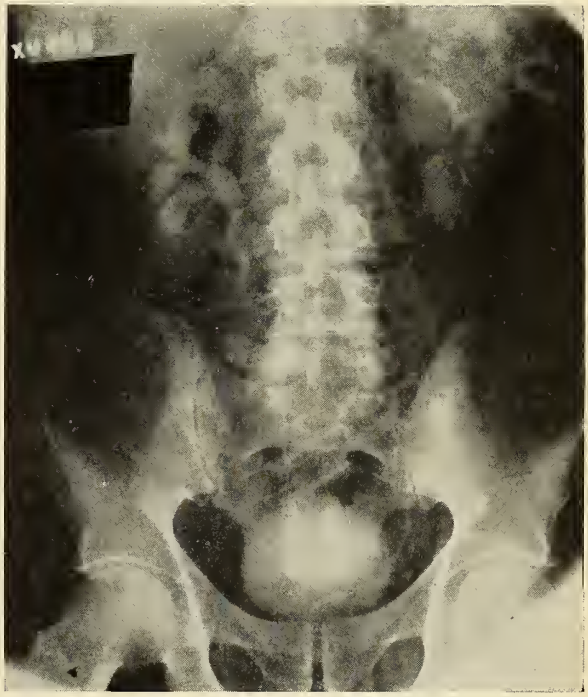

Fig. 1. Excretory urogram showing dilatation of the renal pelvis and calices and upper third of the ureter on the right side.

On March 25, 1944, two days after cystoscopy was performed, the temperature was 103.2° F. There were no physical findings to explain the elevation of tem-

perature. The patient complained of pain in the right groin and hip, and at this time he began to complain of weakness in the right leg. The fever subsided in the next few days. On March 1, 1944, pitting edema of right lower extremity was noted. Arterial pulsations were normal and the temperature of the skin of the right leg was increased. A consultant made a diagnosis of thrombophlebitis of the right iliofemoral vein and suggested that a pelvic lesion might be pressing on the femoral vessels and causing the thrombophlebitis.

On March 27, we were able to palpate a definite mass in the right lower quadrant of the abdomen. There was rigidity of the right rectus in the lower half and tenderness was present over the entire right lower quadrant and in right flank. During the day, the patient complained of severe pain in right side of abdomen. At 11:30 p.m., he complained of severe pain in right side. Shock developed and the patient died.

Necropsy revealed an arteriosclerotic aneurysm of the right common iliac artery (Fig. 2) which had ruptured and caused extensive retroperitoneal hemorrhage. The aneurysm had caused partial obstruction of the right ureter, hydronephrosis, grade 2, and beginning pyonephrosis. The ureter was compressed between the right common iliac artery and the aneurysm at the point of crossing the artery. The patient also had one stone, 2 mm. in diameter, in lower calix of the left kidney, arteriosclerosis, grade 3, of the aorta and coronary sclerosis, grade 1.

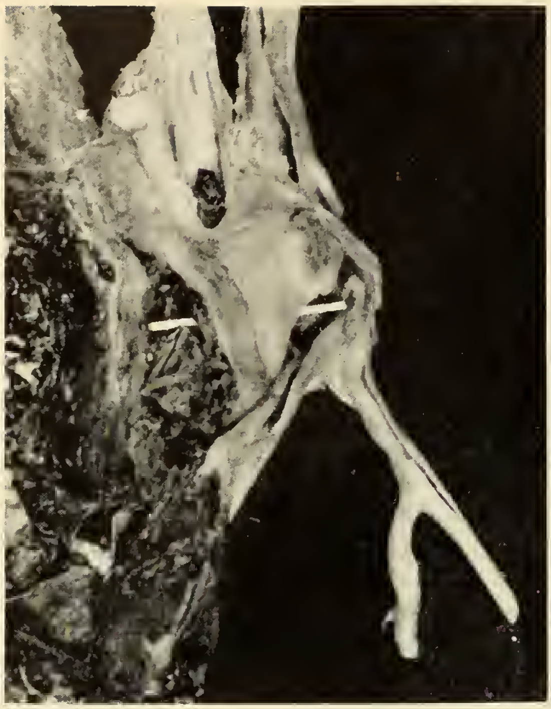

Fig. 2. Aneurysm of the right common iliac artery with clot in place.

116 PHYSICIANS DIE IN ACTION DURING 1945, JOURNAL REPORTS

Death Claims Approximately 4,015 Doctors as Compared with 3,415 During '44; Heart Disease Leading Cause

Death claimed approximately 4,015 physicians during 1945 as compared with 3,415 the previous year, according to the January 19 issue of *The Journal of the American Medical Association.*

On the basis of an analysis of 2,962 obituaries published in *The Journal* during the year, it was found that the average age at death was 65.3, the same as in 1944. The majority of the physicians—494—died between the ages 70 and 74.

Heart disease continued to lead the causes of death among physicians. Coronary thrombosis and occlusion accounted for 655 deaths, 246 occurring between the ages 60 and 69. Cancer and tumors accounted for 296, and pneumonia claimed 145 doctors.

Of the 25 suicides recorded, 11 were the result of bullet wounds, three of a cut artery and three of drugs. There were 87 accidental deaths and 33 of them involved automobiles.

Among the decedents were 256 who had been teachers in medical schools, of whom 97 had reached professorial status. There were eight deans, one of whom had also been president of a medical college, two principals of a high school, two teachers in public schools, one of whom had been head of the business and practice department of the city's high schools, and 78 members of education boards. One hundred and forty-four had been health officers.

The 2,962 *Journal* obituaries included 116 physicians who were killed in action during World War II and 118 who died while in military service. Nineteen physicians lost their lives in the Pacific area, 13 in Germany, 12 each in the European Theatre of Operations and in France, and 11 in Okinawa, including six who were lost in the attack on the *Comfort.*

Of the 118 physicians who died while in military service, aircraft accidents caused the deaths of 22 and vehicle accidents of 10. Heart disease accounted for 25 deaths, 12 of which were attributed to coronary thrombosis. Cancer caused 13 deaths.

The 116 deaths classified killed in action give an average age of 33.0, while the 118 who died while in military service average 40.1. By combining the two, an average age of 36.6 is noted.

Of the seven U. S. Public Health Officers whose deaths were recorded, one died when he slipped on the Jacob's ladder while assisting wounded aboard ship and one when his ship was destroyed in enemy action.—*A.M.A. News,* Jan. 17, 1945.

NOTES ON THE HISTORY OF MEDICINE IN HOUSTON COUNTY PRIOR TO 1900

By NORA H. GUTHREY†
Mayo Clinic
Rochester, Minnesota

(Continued from January issue)

J. M. Riley, who was a native of White County, Illinois, was born on January 18, 1833. A graduate of the Eclectic Medical Institute at Cincinnati, Ohio, in 1859, he came in the following year to Brownsville, Houston County, Minnesota, where he announced himself as physician and surgeon and where he remained, through the boom days of the village and into the period of its decline, at least as late as 1899, according to an old gazetteer and business directory. Dr. Riley was a Mason. In 1870 he served as county coroner and in 1879 he was elected from the first district as a representative in the state legislature. After 1883 he practiced medicine under a state exemption certificate.

Captain See was discussed fully in paragraphs about Brownsville Township, in the narrative preceding this series of biographical notes. Supposedly the possessor and user of medical knowledge, and said to have been in Brownsville during or after the Civil War, he proved on investigation to have been not a physician, but Captain Charles H. See, of Caledonia, Provost Marshal and President of the Enrollment Board of the First Congressional District, which included Houston County. He undoubtedly was at times in the county in the course of duty, and inasmuch as his fellow members on the board were physicians and because much of the work of the board had to do with claims for exemption based on physical disability, there is reason for local mention of Captain See as a physician.

Edwin M. Sheldon, of the regular school of medicine, came from Illinois in 1881 and for about two years practiced medicine in the village of Houston. In 1882 his office was in Field and Briggs' building and he was boarding at the Sherman House. It appears likely that he and Dr. Timothy A. Pope were removing from the village at about the time that Dr. H. P. Johnson settled there. Although Dr. E. M. Sheldon may have been related to the branch of the Sheldon family to which Dr. G. J. Sheldon belonged, such assumption has not been borne out by information at hand.

Giles James Sheldon, tall, slender, blue-eyed, mentioned often in these pages, was one of the earliest settlers and, it is believed, the first physician of Houston County, who arrived on June 27, 1853, at Brownsville, in Brownsville Township.

He was born at Norway, Herkimer County, New York, on May 12, 1806, the son of Caleb Sheldon, a farmer born of English parents, and Rebecca Giles Sheldon, of English descent, a native of New England. In his genealogy of the Sheldon family for four generations Dr. Sheldon mentioned that three Sheldon brothers, who were English seamen, came to America to escape King Charles II; their descendants became farmers. In his immediate family he referred to only one brother and one sister, G. W. Sheldon and Clotilda.

A frail child and youth, Giles J. Sheldon received his early education at home from his mother, who gave him excellent grounding for his subsequent cultural and scientific training. When he was fifteen years old, he entered Fairfield Academy, at Fairfield, New York, on February 5, 1821, and there studied as his health permitted. On February 9, 1826, he entered Lowville Academy, at Lowville, in the state, and the following year, he enrolled at Union College in Schenectady. In June of 1829 he registered at Camden Academy, at Camden, New York, but returned to Union College, where he was elected to the Phi Beta Kappa fraternity and where, in 1830, he received his degree of Bachelor of Science. For two years he studied theology with the expectation of becoming an Episcopal clergyman, but, influenced by his uncertain health, he transferred to the study of medicine. During the years from 1831 to 1833, inclusive, he studied botany, chemistry and medicine at the College of Physicians and Surgeons of the University of the State of New York, at Fairfield; he received instruction in anatomy and physiology from James McNaughton, M.D., and P., and on completion of his work with Dr. McNaughton received certificate No. 165, dated October 30, 1833. At the beginning of the following year, on January 21, he was graduated as Doctor of Medicine. There is record in his private papers that he studied also under several physicians in New York and in Philadelphia, among whom were Dr. Loon (?) and Dr. Booth, and under Dr. Willoughby, of Newport, and that in the intervals of studying medicine he was engaged in farming and surveying.

Dr. Sheldon began medical practice in Norway, New York, in February, 1834, but late in June of that year he removed to Trenton, in Oneida County. On April 10, 1835, he was appointed postmaster at Holland Patent, New York, and served until he moved to Van Buren Harbor, New York, where he practiced medicine in 1836 and 1837. On December 2, 1835, he had been appointed surgeon for the Fourth and Fifth Brigades of Riflemen of the State of New York, an appointment in which he was qualified on March 30, 1836. In 1837 he traveled to Illinois, a state that was the field of his medical practice for three years. In 1840 he moved to Ohio and for the first two years practiced at Amanda. From December 3, 1841, to April 24, 1849, he was in Mercer County, practicing medicine and, for the latter part of the period, living in the village of Mercer and studying law in addition to carrying on his medical work. Thereafter, in Celina, Mercer County, he combined his study of law with his other pursuits to such purpose that he was admitted to the bar on August 5, 1852. On April 20, 1853, he left Celina with his family for southeastern Minnesota in the hope of improving his health, which never had been robust.

Giles James Sheldon's first marriage was to Elizabeth Cullum. His second marriage was to Margaret Roberts, of Celina, Ohio, a native of the state, of Welsh and Swiss descent. Of the second marriage there were seven children: James Giles Sheldon, a railway engineer; Elizabeth Sheldon (Mrs. Reuben) Hoag, a teacher; Celina Sheldon (Mrs. H. J.) Herzog; Henry Robert Sheldon, a farmer; Sumner S. Sheldon, a farmer; Florence H. Sheldon Carrick (wife of The Reverend A. R. Carrick), and Julia Sheldon (Mrs. W. J.) Evans, who in 1941 was the only one living.

On June 27, 1853, to repeat, Dr. Sheldon arrived with his family at Wild Cat

Bluff or Brownsville, Houston County, where he soon bought 160 acres of land for $600. As there were only four families in the settlement, his medical skill was not demanded immediately to any great extent, but his legal knowledge soon was useful, for within a year he was presiding as judge at the first court held at Brownsville. And obviously he entered into community life, because on July 4, when a great barbecue was to be given at Brownsville in celebration of the day, Dr. Sheldon was one of the committee in charge of the arrangements. The following year, on November 9, he moved with his family to Mound Prairie Township and there, near the village of Mound Prairie, he established a large farm, the working of which in later years he turned over to his sons. It was characteristic of him throughout his career that he combined with his professional pursuits the occupation of farming.

Dr. Sheldon's broad professional training made him a most valuable citizen in the pioneer region. As noted, he was elected the first judge of probate in Brownsville, in 1854; in 1860 and again in 1862 he was elected court commissioner. Early convinced of the necessity of establishing settlements, he surveyed, platted and named the village of San Jacinto, secured for it a post office and acted as the first postmaster, and in the same period of the fifties he platted the village of Sheldon, in Sheldon Township. In 1859 he was one of the second board of supervisors of Houston County and, when the change was made from the system of government by supervisors to that of commissioners, in 1860, he was again a member of the county board. In 1863 he served as county coroner.

An able physician and surgeon, Dr. Sheldon often was called in consultation by other physicians in difficult cases. In his diaries, mentioned previously, he wrote of Drs. Train, Fox, Gates, White, Cowles, O'Connor, Bowen and Pope. An untiring student, a cultured and well-educated man, he possessed a good medical and general library, at one time the finest in the county. In the years in which the question was an issue, he was a vigorous opponent of Negro slavery.

On the farm in Mound Prairie Township, serving the community in many capacities, Dr. Sheldon lived until 1880, when death resulted from a stroke. Well-deserved tribute was paid him by all who knew him in recognition of his ability, his ambition and public spirit, the multiple civic and professional services he rendered in spite of his handicap of frail health, and his unfailing consideration of the sick and distressed. Mrs. Sheldon survived her husband many years and died in 1908, having shared with him the honor and esteem of the community.

Dr. Sheldon left many diaries, books, letters and instruments of historical interest and value which at the time these notes were written were in the possession of his grandson, Sumner S. Sheldon, Jr., of Houston.

Rolland Fuller Sheldon, who was to combine the offices of physician and clergyman, was born at Grafton, Vermont, in 1825, the son of Abraham Curtis Sheldon, who was a lineal descendant of Isaac Sheldon.

Isaac Sheldon, around 1640, emigrated from Derbyshire, England, to New England, America, and was one of the founders of Windsor, Connecticut, and Northampton, Massachusetts. To him and his wife were born fourteen children, nearly all of whom married and left children, who dispersed into various parts of the country, so that the Sheldon stock has been widely scattered. Of this family of fourteen, Abraham C. Sheldon was graduated from Yale University in 1812, taught in Middlebury Academy, Vermont, and about 1831 removed from Vermont to Portage, New York. When he was killed, in February, 1834, in felling a tree on his own land, he left his wife and seven small children to face pioneer existence in the great forest region of western New York. The children held together under the influence of their intelligent and able mother, won through to education and useful lives.

Rolland Fuller Sheldon became a master in many lines of work. He was carpenter and blacksmith, musician and music teacher, and in these and various other capacities he earned his way to the degree of Bachelor of Arts at the Baptist University of Rochester, New York, which was then a small institution of less than 300 students. Graduated in the class of 1856, he stayed on in Rochester through 1857 to study theology and medicine in preparation for becoming a foreign missionary. The university did not offer a medical course and Mr. Sheldon studied and practiced medicine with one of the leading physicians of the town. In 1858, therefore, when The Reverend Mr. Sheldon and his bride, Mary Adel Sheldon, arrived at the village of Sheldon, Sheldon Township, Houston County, Minnesota, as home missionaries, (having given up the idea of foreign service) of the Baptist Church, this young physican-clergyman was the possessor of as thorough preparation for the practice of medicine as were many of his solely medical contemporaries.

The village of Sheldon, which Dr. Sheldon made his headquarters, had been founded in 1854 by one of his cousins, Julius C. Sheldon, of Suffield, Connecticut, and platted by Dr. Giles J. Sheldon, to whom he is said to have been distantly related. Beautifully and well situated though it was, accessible by valleys in all directions, the settlement did not become the county seat, as was hoped by its founder, but became one of the disappointed hamlets left to one side by the railroad in 1866. Letters and documents in the possession of Dr. Sheldon's son show that this pioneer physician and clergyman traveled with horse and buggy not only in his own township and county but also over much of southeastern Minnesota, carrying his ministry of grace and healing from the Mississippi River as far west as Carimona and Cherry Valley, in Fillmore County, and as far north as Chatfield, in Fillmore and Olmsted Counties, and Winona, in Winona County. He was a leader in the settlement and organization of this entire territory. In 1860 he was an ardent advocate of Abraham Lincoln for President and, when the Civil War broke out, he was active in raising money and recruiting men for defense of the Union; although because of his dependents, a wife and two small children, he did not enlist; he was unremitting in his patriotic efforts. His younger brother, Abraham Sheldon, of Cherry Grove, enlisted in the army for defense of New Ulm and Fort Ridgely during the uprising of the Sioux Indians in 1862.

When an epidemic of black measles in virulent form broke out in the Norwegian settlements of Black Hammer Township in 1863, Dr. Sheldon was tireless in the campaign to combat the lethal disease, carrying medicine and counsel to afflicted homes, as was customary in the office of the physician in those days. Repeatedly exposed to the disease and overweary, he was already sickening when one night he was caught in a violent rainstorm as he drove home from an errand of mercy to Black Hammer. The next day he came down with the measles and on April 3, 1863, after a few days of raging fever and delirium, he died. He was buried in the old Pioneer Cemetery in southwestern Caledonia in the lot adjoining that of the Trask family, who were among his closest friends.

Dr. Sheldon kept always a large supply of medicines in an old-fashioned red chest that he and his wife had brought from the East, and after his death Mrs. Sheldon dispensed these drugs as he had taught her to do. In the succeeding years, during the Civil War and later, Mary Adel Sheldon, a well-educated woman, taught school in Caledonia, Yucatan, Winnebago Valley, Looney Valley, Sheldon and Houston, all in Houston County. There remains record in old files of Caledonia newspapers of a great patriotic parade, during the war, of all the children of the Caledonia schools, led by Mrs. Sheldon.

In 1943 there were living, among other relatives of Dr. Rolland Fuller Sheldon, his son, Addison E. Sheldon, Superintendent-Secretary of the Nebraska State Historical Society, at Lincoln; his grandson, Philip Sheldon, and his great grandson, Keith Sheldon, both, also, of Nebraska.

Trond Neilson Stabo, born in Norway in 1869, was graduated in 1894 from the Fredericiana University (Kongelige Frederiks Universitet) at Christiania (Oslo). Not long afterward he migrated to the United States and came to southern Minnesota, and on October 8, 1895, he was licensed to practice in the state. On the following October 17 the certificate was recorded in Houston County.

A resident of Spring Grove, Dr. Stabo was a well-known practitioner throughout the county and in contiguous counties. It has been recalled that he was probably one of the first in the county to perform surgical operations for appendicitis, and that he owned one of the first automobiles in the region of Spring Grove and Caledonia. In those days, according to an early citizen of Caledonia, there were no real automobile mechanics and in the smaller towns when anything went wrong with an automobile, the blacksmith worked on it. Dr. Stabo, on one occasion having difficulty with a new car which was giving out clouds of black smoke, was insistent that the magneto should not be touched because, he said, it was sensitive, as stated in the directions that had come with the car. When the difficulty had been corrected as a result of tactful adjustment by the mechanic, who it happened was not a blacksmith, and the doctor was able to continue his rounds with a perfect running car, he returned and paid generously for the correction.

Dr. Stabo was a member of the Houston-Fillmore County Medical Society, the Minnesota State Medical Association and the American Medical Association. In 1907 he moved to Decorah, Iowa, where, in 1943, he was still practicing.

Of **E. D. Stewart,** said to have practiced in Houston County, information has not been available.

Gilbert Thomas was listed in a commercial directory of the late seventies as a physician in the village of Yucatan.

Isaac Whittington Timmons, born on October 11, 1833, on a farm near Chillicothe, Ross County, Ohio, was to become one of the well-known pioneer physicians of southern Minnesota, in Houston, Fillmore and Winona Counties. He was the son of Thomas Whittington Timmons, whose father had come from England with Lord Baltimore and had settled in Baltimore (at first called St. Marysland), Maryland. Isaac Timmon's mother was Hetty Draper Timmons, educated in Philadelphia, the daughter of a Quaker family of Delaware which included a son who became a physician. Thomas Timmons married a second time, a younger sister of Hetty Draper, and of the marriage there was one daughter, Hester.

Isaac Timmons received his early education in the private and public schools of Chillicothe until, in 1851, when he was eighteen years old, he took up his residence in Matamore, Illinois. About three years later in Matamore it happened that he was obliged to go into court for settlement of a dispute, and his attorney was none other than Abraham Lincoln. The difficulty was occasioned by the fact that Mr. Timmons had been elected to the office of town clerk two days before he was twenty-one years of age. He was notified, on his birthday, of his election and on the following day, after being duly sworn in, he gave bonds. Mr. Lincoln, when the legality of his assumption of office was contested, offered his services as defending attorney and brought Mr. Timmons through a victor. At that time Mr. Lincoln remarked that the boy had begun office-seeking early in life and added, when told that friends had been responsible for the candidacy, "It is well to have a good lot of friends when you run; I have met defeat once or twice because I didn't have quite enough."

In the middle fifties Isaac Timmons studied medicine under the preceptorship of one of his brothers, who was a physician, but the instruction was interrupted when in the late fifties he moved to Cairo, Illinois, to engage in the mercantile business with another brother. In Cairo, at the southern tip of Illinois, separated from slave-holding territory only by the Ohio and the Mississippi Rivers, he served as a member of the common council in 1860 and 1861 at the time, just before and after the outbreak of the Civil War, when excitement ran high along the border. By 1862 he had settled in Centralia, Illinois, where for the next eight years he was employed in the service of the government as deputy collector of internal revenue for some eleven counties. During those years he was associated with Robert Noleman, uncle of William Jennings Bryan, and grew to know Judge Bryan, father of "Little William," who then was four or five years of age.

During his residence at Centralia, Isaac Timmons studied law and served as police justice, but law did not appeal to him and he returned to the study of medicine. In 1870, after a course of study of three years at the Homeopathic Medical College of St. Louis, Missouri, he was graduated with the degree of Doctor of Medicine, and in the same year he entered the state of Minnesota to practice medicine for a short time in the little village of Money Creek, in Money Creek Township, Houston County.

For the next twelve years he was, as his daughter has described him, "the proverbial rolling stone." In the early seventies he went to Winona, where he practiced in partnership with Dr. T. Pierce. The pioneer river town disappointed him, however; the levee was a sand and gravel bank and the streets were full of mud and holes. A few plank walks were to be found, but a "general untidy state of affairs existed." Years later he was very proud of Winona, and justly, for he had played a part in building up the beautiful city.

After two years in Winona, in 1877, Dr. Timmons returned to Houston County, this time to the village of Houston, where he stayed until 1881. Besides carrying on a general medical practice he served as justice and as county physician. In 1881 he went to North La Crosse, Wisconsin, but on learning that Chatfield, Fillmore County, Minnesota, was in need of a physician, he settled there for a year and a half. In the early spring of 1884 he returned to Winona where he built up a successful practice and remained there until his death thirty years later. After 1887 he practiced under the Affidavit Ruling.

Isaac W. Timmons was married, in 1857, to Ursula E. Robinson, of Chillicothe, Illinois. Dr. and Mrs. Timmons had six children, Virginia, Jessie, Kate, Lida, Luetta and John W. Timmons. Mrs. Timmons exerted a gentle and understanding influence on her husband's career. In later years the doctor always referred to their life together as "a continual Indian Summer." In 1907, when Dr. and Mrs. Timmons celebrated their golden wedding anniversary in Winona, all but two of the children were living and present. In 1941 only one, Luetta (Mrs. C. A. Peiffer, of Winona) was living. The son, John Whittington Timmons, was for many years, until his death in 1918, a teller of the First National Bank of St. Paul. Kate died in 1937 at Long Beach, California, at the age of eighty-two years. Lida, the wife of C. F. Spencer, who was editor of the *Willmar Journal* for many years, died at Willmar, Minnesota, in 1941. Virginia ("Jennie"), who did not marry, taught school for many years; she died in Kansas City previous to 1907. Jessie, who was married, also died before 1907.

Dr. Timmons was a great reader and student who always took a keen interest in politics. He used neither alcoholic liquor nor tobacco, was a member and supporter of the Methodist Church, and was generous in giving his professional services to those who were unable to pay.

On October 9, 1912, two days before his seventh-ninth birthday, Dr. Timmons died from a stroke.

Hamilton B. Train was born in St. Lawrence County, New York, on April 26, 1825. By 1847 he was in Wisconsin, studying medicine and, after he had settled in Fond du Lac, preaching the gospel. Because of ill health he was obliged to give up the ministry and shortly thereafter he enrolled at Appleton University for a period of medical study. After his return to Fond du Lac he was married to Angelina Clark, on March 27, 1850. Dr. and Mrs. Train had four children, of whom two were living in 1882 (the date of the last published comment available).

In 1856 Dr. Train, a physician of the regular school, came to Minnesota and in the following year to Hokah, in Hokah Township, Houston County, where Dr. Charles Jenks was the only practitioner of medicine, having arrived a short time previously in 1856. Hokah was then at the beginning of a period of mounting prosperity which continued until 1872 when, with the reduction in status of the railroad shops and the corresponding reduction in population and business enterprises of all types in the community, a permanent decline began. Dr. Train, well established, early had built up an excellent practice and he made Hokah his permanent home. In 1880 and 1881 he was serving as health officer for the township during an outbreak of smallpox in the locality. After the "Diploma Law" of 1883 came into effect he practiced under a state exemption certificate. He died in Hokah on July 28, 1891, thirty-four years after his arrival in the village. Mrs. Train continued to make her home in the village after her husband's death.

Dirk Van Krevelen was born in Holland in 1828. His preliminary education and his academic collegiate training he received in his native country and his medical education, at the universities of Germany. It has been said that he arrived in Baltimore, Maryland, in 1854 and that soon afterward, accompanied by his family, he went to Valparaiso, Chile, on appointment as superintendent of a marine hospital there. During a political and religious uprising in Chile in 1858 and 1859 he, together with his wife and children, was rescued from the city by a sloop-of-war, but only after they had experienced severe difficulties and hardships; ultimately they returned to Baltimore. During the Civil War Dr. Van Krevelen served as surgeon on the field and in hospitals. After the war he spent a year in Europe in medical study and in renewing old friendships, and on his return to the United States, settled in Grand Rapids, Michigan, and there practiced medicine.

In 1849 Dr. Van Krevelen was married for the first time. His wife died in 1867 and in 1873 he was married to Gertrude Edons, like himself, a native of Holland.

By 1879, at the latest, and perhaps a year or two earlier, he was in Belle Plaine, Minnesota, and it has been said that he moved there from Hokah, in Houston County. An able physician and a well-liked, genial man in Scott County, as elsewhere, he won friends and confidence and had a good practice. In 1880 he served as county coroner. By 1888 he had settled in Carver County, near New Germany, where he bought a general store, which he proceeded to expand. Not of mercantile taste, however, he soon sold out and next chose Waconia as his field of professional endeavor. In 1897 he moved with his family from Waconia to Silver Lake, in McLeod County. In the official register of 1883-1890 of licensed physicians in Minnesota he was listed, without specified residence, as the holder of an exemption certificate.

M. J. Veiling (Velling?) probably was one of the first few physicians, certainly he was among the earliest group of physicians, in Caledonia and in the county. It appears from early records that he was the second coroner, in 1857, of Houston County and that he was succeeded in the office some time prior to 1868 by Drs. Harvey B. Laflin and Timothy A. Pope; Dr. Veiling served a second term in 1862. It is hoped that more will be learned about him, perhaps through reports on early physicians in different parts of the state.

Charles H. Wagner, possibly the Dr. Charles H. Wagner who was more closely identified with Fillmore County in later years, was listed in a business gazetteer of 1880 and 1881 as resident in Money Creek, Houston County.

S. C. White was mentioned by Dr. Giles J. Sheldon in his diaries as a contemporary physician in Houston County, obviously some time during the period between 1853 and 1880. It is known that in 1881 and 1882 Dr. White was serving as health officer in the village of Hokah at the same time that Dr. H. B. Train was health officer for Hokah Township and that Dr. W. W. Holden was health officer for Union Township. Not to confuse the issue, but rather to note the possibility of a misprint in initials of the same man, it should be stated that in the autumn of 1871 a Dr. A. C. White, physician and surgeon, lately of Muskegon, Michigan, opened an office in Preston, Fillmore County. Changes of residence from county to county were common among physicians in those years and it is possible that Dr. White subsequently settled in Houston County.

(To be continued in the March issue)

President's Letter

Two items of economic development in medicine, which have recently come to the attention of the Council and officers of the Association, are of such vital concern to the entire membership that comment upon them now seems to be an urgent necessity.

The first of these is the prediction that the Wagner-Murray-Dingell Bill may pass at this session of Congress. To accomplish this, the authors of the bill have deleted from it all clauses involving the appropriation of funds. This has been arranged to ensure consideration of the bill by a committee friendly to it. Favorable action on a bill by the committee to which it is referred is followed by its introduction to the entire Senate with the recommendation by the committee that it be passed.

These facts mean that any opposition to the bill will have two opportunities to defeat it. The first opportunity will be on the floor of the Senate where it is subject to debate by the entire Senate prior to its being voted upon. If the opposition to the bill can summon enough strength on the floor of the Senate, the act can be defeated by general vote of that body. In spite of a press poll of the Senate indicating the bill's defeat, some predictions are that this is not likely. The second opportunity to prevent its full enactment will be in defeating the appropriation bill which will have to be passed later to provide the funds necessary to carry out its provisions. At present, the latter course appears a more likely point of obstruction than defeat of the initial bill on the Senate floor.

It should be borne in mind that under the present system of medicine in the United States, health, mortality and longevity are better than those of any country in the world. The issue in the Wagner-Murray-Dingell Bill is supposedly the reduction in cost of medical care. In every instance where compulsory Health Insurance has been inaugurated to reduce the cost of medical care, quality of medical care has been sacrificed. So, in the present instance of the Wagner-Murray-Dingell Bill, the important fact is that not only is the American System of Medicine at stake, but, of far greater importance, the actual health, lives and longevity of the people of this country are being voted upon in the halls of Congress.

The second matter of economic importance to the profession is the reorganization of veteran medical care. Veterans Hospital facilities in Minneapolis are being integrated with those of the Medical School and University Hospital. Veterans Administration branch offices are being established throughout Minnesota. Medical care of the veteran in his home community may be provided by the Veterans Facility in accordance with a plan now being arranged by a committee of the Minnesota State Medical Association.

At the Veterans Hospital in Minneapolis, all physicians will be enrolled in residencies or fellowships with University Hospital and Medical School faculty members serving as consultants or senior consultants. All gradations of physician appointments will be co-ordinated with postgraduate medical education so that each staff member may, under the guidance of proper authorities, ultimately become a diplomate of some specialty board.

In order to facilitate medical care of the veteran in his home locality, branch and administrative Veterans Facility offices are to be established in a number of the cities scattered throughout the state. Through these offices, physicians called in attendance of a veteran in his home can secure, by telephone, permission to provide medical care. It is expected that both administrative and medical personnel will be found in the branch offices.

For the preparation of details of a program to render medical care to the veteran in his home community, a committee of physicians has been appointed for the Minnesota State Medical Association. The committee consists of physicians who served in this or the first World War. All sections of the state and all branches of the military service are represented on the committee. Fee schedules for such veteran medical care are being promulgated. Service connected and nonservice connected disabilities are receiving consideration. As soon as a comprehensive, detailed plan is completed, it is to be sent to Washington for approval. All of these developments are in the process of completion. Details will be provided as they are available.

IMPROVED VETERANS' FACILITIES

THE veteran of World War II is going to be provided with the best possible hospital care. For some time considerable criticism has been voiced of the quality of care being furnished by the Veterans' Facilities.

Recently the President signed a bill which provided for Medical and Surgical Departments in the Veterans Administration. More than that, arrangements have already been made for the employment of specialists on certain medical school faculties on a half-time basis to care for these veterans. These new appointments have already been made in Minnesota by the Dean of the Medical School who with a medical faculty committee will supervise their activities. Civil Service will no longer designate appointments. It is understood that medical personnel in the Veterans' Facilities who hold their appointments under the Civil Service will be retained unless there is good reason to dispense with their services. Even though Civil Service appointments eliminate the undesirability of political appointment, it has long been recognized that the difficulty in dispensing with Civil Service appointees is at times a handicap.

Residents and interns at these Veterans' Hospitals will be appointed by the medical school which will have direct supervision of their activities. The value of residencies and internships in these hospitals to recent graduates and returned medical officers is likely to be secondary to none, and the new setup helps solve a pressing need. This presents a happy solution of a difficult problem.

Steps are being taken for a better solution of the care of the returned veteran who is in need of medical care for disabilities sustained in service but who does not perhaps need hospital care, who lives distant from a Veterans' Hospital or for whom perhaps there is no room at present in a Veterans' Hospital. There will undoubtedly be two or three times the demand for medical care on the part of veterans of World War II as there were following World War I. How can this best be provided? It is the idea of Major General Hawley, chief medical director of the Veterans Administration, that the medical profession of each state present their own plans for his consideration.

The medical profession of Michigan has already submitted its plan whereby the members of the Medical Services, Inc., of Michigan will provide medical care for veterans outside of the Veterans' Hospital on a fee basis acceptable to the members of the Michigan State Medical Association. Steps are being taken to provide hospital care also through the Blue Cross hospital organization in Michigan.

Personally, we can see no need for any other organization than the State Medical Association when it comes to considering ways and means for providing this medical service for Veterans of World War II who do not require care in a Veterans' Hospital. All that would be necessary would be an agreement on fees for certain services and an indication of willingness on the part of the member to fill out certain forms. We have a committee of our State Medical Association working on the project now.

Following World War I methods adopted for providing for disabilities of veterans were often extravagant in time and money in that veterans were required to travel long distances to receive medical aid. Utilization of the services of the veterans own medical advisor would eliminate this unnecessary expense. The local physician can care for veterans suffering from certain disabilities in the home or local hospital, without necessitating care in a Veterans' Hospital.

SCHEMM TREATMENT OF EDEMA

IN April, 1942, Dr. F. W. Schemm of Great Falls, Montana, read a paper[1] before the annual meeting of the American College of Physicians, in Saint Paul, on the value of a high fluid, a low salt and sodium intake and an acid ash diet in patients suffering from edema from any cause and especially from heart disease. Before this paper was published another[2] by the same author appeared. In spite of the array of cases scientifically studied and the most favorable results reported, the profession has been slow in accepting his contribution.

In spite of numerous authoritative statements which have appeared in the literature during the past hundred and fifty years on the value of water as a diuretic, the medical profession today is rather generally disposed to restrict fluids in edema from any cause. This is apparently wrong and not only adds to the discomfort of the patient but may even result in a dehydration of tissue cells and a lessening in the elimination through the kidneys of the sodium chloride and sodium bicarbonate contained in the edema fluid.

Schemm argues the logic of reducing to a minimum the sodium chloride and soda intake in the diet and prescribing an acid ash diet to aid the neutralization and elimination of the sodium bicarbonate in the edema fluid, although the acid normally formed in the tissue will be sufficient in many cases. He sometimes adds acid in the diet in the form of dilute HCL acid or ammonium chloride to assist this process.

Foods that produce an acid ash are meat, fowl, fish, eggs, cereals (except corn) prunes, plums and cranberries. All other foods yield an alkaline ash.

His treatment consists of forcing liquids, particularly water, and giving a neutral diet consisting of low salt, low sodium and an acid ash diet. No food containing salt and no soda are allowed. Small amounts of milk and certain vegetables and fruit are allowed in addition to the acid ash foods.

Digitalis, when indicated, should of course be continued. Murcurial diuretics may also be used although they are seldom needed in obtaining diuresis.

Schemm's detailed reports of his success are most convincing, and trial of his method has confirmed his observations.

DRUGGISTS IN DISTRESS

PROVIDING the druggist with prescriptions for narcotics before the prescription is filled oftentimes causes delay or inconvenience for the physician or patient or both. When the prescription is for a simple cough syrup containing codein which is needed to help the patient through the night, the insistence on the part of the druggist that he have the written prescription before he delivers the medicine may seem unreasonable to the physician.

Nevertheless, the Bureau of Narcotics is responsible for the proper dispensing of narcotics and has established the following regulations:

> **Article 172—Bureau of Narcotics Regulation No. 5**
>
> *Telephone Orders*—The furnishing of narcotics pursuant to telephone advice of practitioners is prohibitive, whether prescriptions covering such orders are subsequently received or not, except that in an emergency a druggist may deliver narcotics through his employe or responsible agent pursuant to a telephone order, provided the employe or agent is supplied with a properly prepared prescription before delivery is made, which prescription shall be turned over to the druggist and filed by him as required by law.

There is reported to be a scarcity in the illicit traffic of narcotics. The addict will usually go to any length to satisfy his craving. It is not unusual for him to call the druggist, posing as a physician and ordering a narcotic. There is good reason, therefore, for insistence on the part of the Bureau of Narcotics that the druggist have the physician's prescription in his hands before he furnishes the narcotic. Too often the physician becomes irritated with the druggist who seems to be lacking in co-operating with his patron, the physician. The Narcotics Bureau, however, is clamping down on druggists who fill narcotic prescriptions over the telephone. Under the circumstances, one cannot blame the druggist if he is meticulous in observing the letter of the regulation.

PENICILLIN ACTION NOT NEW

AN interesting communication from Dr. Russell F. Maddren appeared under Correspondence in the *Journal of the American Medical Association* for January 19, 1946. He refers to a communication from the physicist, John Tyndall, to the English Royal Society, which was published in the Philosophical Transactions in 1876.

Tyndall reported the clearing of exposed tubes containing bacteria and his inability to find any active life in the bacteria in tubes contaminated with surface growths of penicillium glaucum.

Thus the fact that the mold Penicillium inhibits the growth of bacteria was recognized several years ago, but the therapeutic significance of this fact was not recognized until recently. Truly, knowledge comes but wisdom lingers.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

NATIONAL HEALTH CONGRESS PROPOSED

A National Health Congress, as an answer to the threat of government control of the health professions, was the subject of a set of resolutions presented before the annual meeting last month in Chicago of the AMA House of Delegates.

According to Dr. E. S. Hamilton, Illinois, who introduced the resolutions, such a congress is urgently needed to prevent regimentation of the medical profession, to preserve and extend health services for this nation's citizens and to provide a co-ordinating body for all agencies in the health field.

These resolutions represent the first step in making the National Health Congress more than just an idea. It was proposed:

1. That the House of Delegates "recognize the need for a National Health Congress, representative of the medical, dental, hospital, nursing, pharmaceutical and allied professions, and that it approve the creation of such a co-ordinating body."

2. That the House of Delegates instruct the Council on Medical Service and Public Relations to take the initiative and "bring together interested groups to organize and incorporate *immediately* a National Health Congress."

The resolutions were referred to the Reference Committee on Legislation and Public Relations, which reported the resolutions to the floor where they were subsequently passed.

What Is the National Health Congress?

The idea of a National Health Congress has been in the making for a long time. Physicians will be hearing more and more about it in regard to the controversy between those favoring federal control of health services and those of the health professions who contend that this nation's health services must and shall remain in free hands.

Dr. A. S. Brunk, former president of the Michigan State Medical association, was instrumental in formulating a concrete plan for the setting up of a National Health Congress. Collaborating with John R. Mannix, director, Plan for Hospital Care in Chicago, and John F. Hunt, vice president of Foote, Cone and Belding, Chicago, he presented an organizational outline in the October, 1945, issue of "The Modern Hospital." It is this outline that will be described here.

Among the several objectives of a National Health Congress presented in this report are: (1) keeping health protection for the American people on a voluntary basis; (2) insuring the public complete protection regardless of financial status or location; (3) co-ordinating all health agencies and activities; (4) providing a plan for voluntary prepayment of health protection at a cost equal to or lower than any national compulsory health insurance plan; (5) educating the public in health matters with the object of improving national health standards and interesting the public in taking advantage more and more of the facilities for health improvement; and (6) providing incentives for persons engaged in all phases of health work.

How Would It Be Organized?

According to the proposal, the National Health Congress would be patterned after our national law-making body, so that it would not only serve as a forum for free and open discussions on health matters, but would also be endowed with the power to act for the nation's voluntary health forces, which would create it.

As for the membership, it is proposed that the Congress contain one or more representatives of the hospital, medical, dental, nursing and pharmaceutical associations of each state as well as industrial, labor and agricultural associations from every state and representatives from the senate, the house of representatives and the United States Public Health service.

The National Health Congress would concern itself with all measures affecting health care at the national level. The Congress would cover any plan for prepayment of health care by an individual or family unit, and it would recommend to federal and state governments how they might participate in health activities, provide for research and extend benefits to public charges. To carry out the directives of the Congress, Dr. Brunk and his colleagues propose that a National Health Administration be set up under the direct control of the parent organization.

Must Have Permanent Quarters

The planners of the National Health Congress recommend that the Congress have permanent headquarters in some city equally accessible to all members as well as capable of providing facilities for carrying on the administrative functions of the Congress. The body would convene once a year, at least, to consider problems of extension and improvement of the nation's health care; and, since it would be restricted to matters of health alone, it is not anticipated that members will find that serving with the Congress interferes too much with private affairs. Above all, the Congress must have the *power to act* so that the greatest amount of work can be accomplished in the shortest possible time. To expedite the work of the Congress, a system of committees would be set up to study individual proposals before they are voted upon. In this and in other ways, it would borrow the best aspects of the national legislative congress. This, then, is one plan offered as a counter-proposal to the compulsory health insurance plan outlined in the Murray-Wagner-Dingell Bill.

Organization of a Health Congress Forthcoming

From the action recently taken by the AMA, it is evident that machinery will be set in motion shortly to create a National Health Congress, perhaps one similar to that proposed by Dr. Brunk and his associates. In a news letter sent out January 15 by the Council on Medical Service and Public Relations to officials of state associations, the Council reported that the formation of a National Health Congress is one of the very important tasks it is commissioned by the House of Delegates to carry out during 1946, another being the development of a specific national health program. In the words of the Reference committee which presented the resolutions, a National Health Congress "will undertake to bring to all the people of this nation the complete benefits of modern medical-dental science and the finest hospital facilities, will arrange for budgeting the cost of such services at monthly rates within the financial means of all Americans through voluntary, non-profit health plans and will work speedily for the institution of such voluntary non-profit health plans in those places or localities where they do not now exist."

Citing the need for immediate establishment of such an organization, the resolutions stated further: "While each of the groups in the health field has its own organization, working independently for the preservation of the American system of health care, an over-all body or council is necessary to integrate the necessary collective thinking and activity of all organizations or units." For that reason a serious and immediate need exists to develop a working liaison or congress of all agencies in the health field to secure the most effective results of action and public education.

PUBLIC HEALTH PROFESSORSHIP CREATED AT "U"

The University of Minnesota was recently on receiving end of a gift of $150,000, which will finance the University's first permanently endowed professorship. The donor of the gift was the Mayo Properties association.

Salary for the post, to be known as the Mayo Professorship in Public Health, is to be not more than $10,000 annually, and will probably be filled by July 1, according to University authorities.

The University has one other named professorship, the George Chase Christian Professorship in Cancer Research. This chair is not permanent, however, although it is still being maintained by gifts received at the time of the liquidation of the Citizens' Aid society.

The school of public health, which will contain the new post, was created within the medical school two years ago from what was formerly the department of preventive medicine and public health. It will serve as one of this country's six regional training centers, where doctors, engineers and nurses in public health, studying at the graduate level, can become specialists.

VET HOSPITAL EXPANDS MEDICAL STAFF

The recent addition of 146 physicians, many of them nationally known men in their fields, to the Fort Snelling Veterans hospital staff is expected to make the hospital one of the nation's leading veterans' medical centers. A joint announcement of these additions to the staff and plans to have the University of Minnesota medical school take over most of the responsibility for medical services at the hospital was made by Dr. Harold S. Diehl, dean of medical sciences at the University; Carl D. Hibbard, manager of the Minneapolis veterans administration facility; and Dr. Harry E. Bank, chief medical officer at the veterans hospital.

Broad Plan Outlined

A broad program of improvement of facilities of the veterans hospital has been outlined which will add to the staff 35 men to hold the rank of senior consultant, 43 to serve as consultants and 68 resident physicians or fellows. The program provides:

1. Direct supervision of all appointments of doctors to the hospital staff by the dean of the University medical school so as to raise the hospital standards to the level of those of the medical school;
2. The addition to the staff of specialists from all parts of the country to be supervised by a University committee, headed by Dean Diehl;
3. The establishment of a fellowship system and the appointment of 68 "highly selected" University graduate doctors under the system to work full-time in the hospital to receive specialists' ratings; and
4. The appointment of physicians by merit and ability rather than on the basis of civil service status, veterans to be given preference when possible.

Aim to Modernize System

It is reported that the Veterans hospital at Fort Snelling is the second in this country to modernize its system. The purpose of the modernization, according to veterans administration authorities is "to insure that veterans will obtain the same up-to-date medical care and treatment that they would obtain in hospitals attached to the nation's leading medical schools and centers."

Dr. Diehl puts it this way: "This plan will give the veterans the kind of treatment I'd want my own son to have."

Minneapolis Osteopath Pleads Guilty to Criminal Abortion

Re State of Minnesota vs. Madison J. Hampton

On January 9, 1946, Madison J. Hampton, fifty-nine years of age, and licensed to practice osteopathy in the State of Minnesota, entered a plea of guilty in the District Court of Hennepin County, to an information charging him with the crime of abortion. Hampton, who for the past year had maintained an office at 1406 W. Lake Street, Minneapolis, and whose office for fifteen years previous to that time was in the Masonic Temple Building, Minneapolis, was sentenced by the Hon. Arthur W. Selover, Judge of the Hennepin County District Court, to a term of one year in the Minneapolis Workhouse. Upon the recommendation of Mr. Otto Morck, First Assistant County Attorney of Hennepin County, and F. Manley Brist, attorney for the Minnesota State Board of Medical Examiners, Judge Selover stayed the sentence upon condition that Hampton close his office and refrain in every manner, from practicing osteopathy and violating the laws of the State of Minnesota.

Hampton was arrested on December 13, 1945, following an investigation by the Minneapolis Police Department and the Minnesota State Board of Medical Examiners into Hampton's activities. On December 4, 1945, a thirty-four-year-old married Minneapolis woman was admitted to General Hospital, suffering from peritonitis following a criminal abortion. The woman gave a statement naming Hampton as the person who performed the abortion upon her. Hampton, at the time of his arrest, gave a signed statement in which he admitted having performed the abortion by means of "a blunt wire silver instrument" which he used to curette the patient. Hampton also admitted in his signed statement that he was paid $65.00 for the criminal abortion, $35.00 of which he returned to the patient when it became necessary for her to be hospitalized. Hampton also admitted that he had been performing abortions over a period of the past ten years. Hampton stated that he graduated from the Des Moines Still College of Osteopathy and that he had been practicing in Minneapolis since 1920.

EXPERIENCES IN AN EVACUATION HOSPITAL IN ETO

R. E. HULTKRANS, M.D.
Minneapolis, Minnesota

The mechanical operation of an Evacuation Hospital of 400-bed capacity was discussed.

The personnel consisted of thirty-nine officers, forty nurses, and 217 enlisted men. During all of the campaign in France and Germany, this unit functioned in tents except for three months during the winter.

The hospital was transported from one station to another in trucks except at the time of the Rhineland campaign when the entire unit including equipment and personnel was flown in C-47 planes a distance of about 200 miles. The hospital was in operation at thirteen different stations in France and Germany.

Figure 1 shows an average setup of the hospital. The tents used were 40 by 16 feet. The large squares represent two such tents tied together at the sides and set up as a single tent. The double oblongs represent two tents tied end to end.

Figure 2 is a map of the intinerary of the hospital and shows the areas at which the hospital was in operation.

This type of unit proved highly efficient; 20,738 casualties were treated up to V-E Day with a mortality rate of slightly less than 3 per cent. All types of cases of both a medical and surgical nature were handled.

Discussion

Dr. Charles Aling: I think after that excellent discussion by Doctor Hultkrans on Evacuation Hospitals, it is superfluous for me to add anything. I know you realize that no one can claim more experience in an Evacuation Hospital than he. His unit did see a tremendous amount of work. Our unit followed very much the same course, but were a little further north.

We found that we couldn't operate for a too long period of time, for after a definite length of time, one's efficiency would go down. We think we are unique in developing an eight-hour shift. We operated continuously for eight hours, except one-half hour for lunch. Each shift would alternate, reporting for duty every other eight hours. We found also that, by this shift, doctors and nurses had every other evening off. This would be early enough to obtain some recreation to help them forget their troubles. On a twelve-hour shift one would be on days for two weeks, for instance, necessitating the alternate shift being on nights for the same period.

CALCULATION OF DISABILITY IN THE EXTREMITIES

CARL O. RICE, M.D.
Minneapolis, Minnesota

In order to establish a method whereby disability can be standardized, it seems necessary to establish a few dicta by which to guide disability calculations so that the injured individual could be given the benefit of the doubt; whereby the compensation laws can be taken into consideration; and in which the insurance carrier can feel that he is not being required to pay excessively where a relatively minor disability occurred. These dicta are as follows:

1. In one hundred per cent industrial disability arrives somewhat short of 100 per cent uselessness. Most state industrial laws specify that loss of use of a member constitutes loss of that member. This seems reasonable for a member is of no industrial value if it cannot be used, even though it remains attached to the body.

2. Disability of a single joint is a relatively greater handicap to that member, when involved alone, than when involved with other joints. Therefore a single joint must receive a greater relative value in relation to the whole member than it receives when involved with one or more joints of that member. This is in harmony with the industrial law which specifies a greater total value for the loss of a thumb and all the fingers than for a hand.

3. Each joint of a member should be given a specific value in relation to the member as a whole. These relative values should indicate the disability to the member when the joint is completely rigid and unassociated with other disabilities.

4. Disability should be calculated upon objective measurable factors in order that some degree of constancy can be established. The degree of a motion is the most objective measurable factor. Additional estimates of minor value for disability may be added for other factors, not measurable, in order to allow for pain, loss of sensation, in-coördination, lack of power, et cetera. But if the serviceable range of motion is used as the measurable factor, then most of these other factors have been given due consideration. It has seemed to me that methods for culculating disability wherein pain, in-coördination, weakness, adaptability, et cetera, have been given unit values are too intangible to be much more than a good guess, accurate only in proportion to the experience of the physician who gives it.

5. The final percentage of disability in a member should be constant, no matter in what State it exists or in what occupation it occurs. The award for such disability may vary depending upon occupation or other factors, but that is a problem for the Industrial Commission to establish and not a problem for the physician. The loss of an index finger constitutes a loss of 100 per cent whether on a concert violinist or a ditch digger.

6. Disability cannot be measured within more accurate units than five or ten degrees. Therefore, the end result should not be calculated more accurately than in units of five. The end figure should be placed at the closed multiple of five. This I choose to call a disability unit.

It seems further necessary to determine the nature of the existing laws in order that disability evaluations may be compatible with the law.

The law indicates that compensation may be paid on the basis of a specified amount of money, for a specified number of weeks, for a specified loss of a member.

The law specifies these members: a thumb, a finger (index, middle, ring, and little); a hand, a hand and wrist, (or hand and forearm) an entire arm (upper extremity), a great toe, a toe other than the great toe (individual toes not specified), a foot, a foot and ankle, (foot and leg below the knee) a leg through the thigh, an entire leg (lower extremity).

Each disability estimation, no matter how small, must be expressed as a percentage value of one of these. The smallest member into which all of the disability can be included, is chosen as the one on which the disability must be calculated. If the disability lies within a finger, the calculation is based on a finger instead of the hand. If it lies within the hand it is based on the hand instead of the "hand and wrist" or "arm," et cetera.

It therefore becomes necessary to establish a relative value for the various portions of a member, in relation to a whole member, before it becomes possible to calculate disability to the whole of this member, as contributed by one or more of its units (Figs. 1, 2, 3, and 4).

Whenever multiple disabilities exist within one of these members, calculations must be made so that all of the factors can be interpreted in relation to the whole member without greatly exceeding 100 per cent.

I shall endeavor to illustrate in these sketches the method by which disability is calculated. All of the details of my method of establishing these values cannot be completely explained in this brief discussion. More detailed explanations are now being prepared for a later publication.

In that the function of the phalanx is demonstrated through the motion in its corresponding joint, the disability of each phalanx can be calculated by simply determining the percentage of lost motion, out of a possible normal, using the opposite member for the normal standard.

If the distal phalanx of the thumb has lost 35 degrees motion out of a possible 70 degrees, the percentage of lost motion is 50 per cent (35/70 = 50%). A loss of 30 degrees motion in the proximal joint of the thumb out of a possible 60 degrees, likewise, constitutes 50 per cent loss of the proximal phalanx (30/60 = 50%).

The illustration in Figure 1 reveals that each of these joints has a value of 50 per cent of the thumb. Therefore, 50 per cent lost motion in each joint would reveal 50 per cent disability to the thumb on the basis of the following calculations:

50% (loss to distal joint) × 50% (value of distal joint) + 50% (loss to proximal joint) × 50% (value of proximal joint) = 50% (disability to thumb).

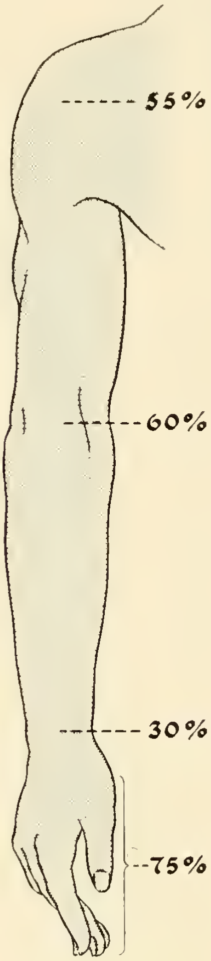
Figure 1, illustrating the index finger, reveals that the distal phalanx has a value of 50 per cent of the finger; the mid-phalanx a value of 65 per cent of the finger, and the proximal phalanx a value of 60 per cent of the finger.



Industrial value of upper extremity
("arm")
200 wk.
40% of "permanent total"

Fig. 4.

The law specifies that the loss of or the loss of the use of a distal phalanx has a value of 50 per cent of the finger. The motion required in the middle and proximal joints to make the finger useful, can justifiably be given more value than the distal joints and, therefore, the value of 65 and 60 to the middle and proximal joints, respectively, can certainly be awarded for these.

These values would be awarded if each of these joints were involved alone, with rigidity. However, if more than one joint were involved with rigidity, their total value would exceed 100 per cent far in advance of complete uselessness. This is indicated in the following equation:

$$50\% + 65\% + 60\% = 175\%$$

It therefore becomes necessary to decrease the value of each additional joint, whenever more than the distal joint is involved, so that the final equation will not greatly exceed 100 per cent, when each of these three joints is completely rigid.

This equation must take into consideration the stipulation of the industrial law which specifies that the loss of use of the distal phalanx is equivalent to 50 per cent loss of the finger. The value of the distal joint accordingly cannot be diminished and, therefore, in the equation, its divisor is designated as 1.

The formula can be expressed as follows:

$$\frac{\%\text{ loss of distal phalanx} \times \text{value of distal phalanx}}{1} + \frac{\%\text{ loss of mid phalanx} \times \text{value of mid-phalanx}}{2} + \frac{\%\text{ loss of proximal phalanx} \times \%\text{ value of proximal phalanx}}{3}$$
$$= \text{disability of the finger.}$$

If the numerical values for each of the joints of the finger, as illustrated in Figure 1, are substituted in this formula, it reveals the following:

$$\frac{50}{1} + \frac{65}{2} + \frac{60}{3} = 102.5$$

The 2.5 per cent excess makes it possible for the fingers to be 100 per cent disabled and still retain 3 or 4 degrees of motion in each of its joints. This seems not unreasonable for such a finger would still be industrially useless, even though attached to the hand.

If we were to assume 50 per cent of the lost motion in each of the joints of the finger, the following formula and percentage disability would be obtained:

$$\frac{50\%\text{ of }50\%}{1} + \frac{50\%\text{ of }65\%}{2} + \frac{50\%\text{ of }60\%}{3} = 51\%$$
(disability to the finger)

Figure 1 also reveals the middle, ring, and little finger with identical value for each joint as has been described for the index finger. Calculations of disability in these fingers is figured in the same manner.

The legal weekly indemnity for each of the fingers is illustrated to be: 60 weeks for the thumb, 35 weeks for the index, 30 weeks for the middle, 20 weeks for the ring, and 15 weeks for the little finger. The hand has a specified legal value of 150 weeks. From these figures the relative values of the fingers and thumb, in relation to the hand, can be calculated. These calculations reveal the following:

Thumb $\frac{60}{150} = 40\%$

Index $\frac{35}{150} = 24\%$

Middle $\frac{30}{150} = 20\%$

Ring $\frac{20}{150} = 14\%$

Little $\frac{15}{150} = 10\%$

Total 108%

The law specifies that the sum of the disabilities in the fingers and thumb cannot be awarded in excess of that which is awarded for a hand. The additional 8 per cent over 100 per cent, as indicated in the total for all the fingers, suggests then, that the fingers need not be completely disabled in order that an award of 150 weeks be given.

The drawing (Fig. 2) illustrates that the thumb and fingers and their respective metacarpals constitute the entire hand.

The apponens actions of the thenar portion of the hand enclosing the metacarpal of the thumb, contributes additional value to the hand not included in that which is manifest by the thumb alone, as illustrated in Figure 1, where the thumb had a value of 40 per cent of the hand.

The thenar portion of the thumb adds 10 per cent to this, making a total of 50 per cent value of the hand for the thumb and its metacarpal.

The metacarpals of the fingers possess no independent value to the hand other than of supporting the fingers which in turn transmit their combined function into a hand. Whatever value the hand may possess, as far as the fingers and metacarpals are concerned, is manifest through the action of the fingers. It therefore seems reasonable, when making a calculation of disability in the hand, to base it upon the function in the fingers and thumb.

Therefore, in order to determine the disability in a hand, the disability in each finger is first calculated as described in the precding paragraphs. This disability is then multiplied by the relative value of each finger in relation to the hand.

The disability contributed by the thumb and its metacarpal is obtained by calculating the percentage of lost motion in each of the joints of the thumb and its metacarpal. These values are multiplied by the relative values of each of these joints and the product is the factor which contributes to the disability of the hand.

If an example can be used assuming 50 per cent disability in each of the fingers and thumb, the following equations will reveal the disability to the hand:

	Disability		Value to Hand		Disability Contributed to the Hand
Thumb-Distal joint	50%	×	20%	=	10%
Proximal joint	50%	×	20%	=	10%
Carpa-Metacarpal joint	50%	×	10%	=	5%
Index finger	50%	×	24%	=	12%
Middle finger	50%	×	20%	=	10%
Ring finger	50%	×	14%	=	7%
Little finger	50%	×	10%	=	5%
Total	50%	×	118%	=	59%

The excess of 18 per cent in the total values, constituting the hand, would allow approximately 10 degrees motion in each joint of the fingers and thumb and still retain 100 per cent industrial disability. A hand with only 10 degrees motion in each of its joints would not constitute an industrially usable hand.

It seems justifiable to be generous to that extent in calculating a disability. Furthermore, it seems legally warranted to be generous to that extent, for, wherein the law specifies a total weekly indemnity for the loss of all of the fingers and the thumb of 160 weeks, it specifies only 150 weeks for a hand. The law further specifies 175 weeks for a "hand and wrist." A complete analysis of all the fingers and the thumb including their metacarpals would constitute, for practical purposes, the loss of use of a hand and wrist. Therefore, 118 per cent disability of 150 weeks would be equivalent to 177 weeks, which is only one-half week in excess of the indemnity of a hand and wrist. This seems to indicate that the values which I have chosen are accurate enough.

Figure 3 discloses the industrial member of "hand and wrist." A hand and forearm not including the elbow joint is perhaps anatomically more correct.

It has already been stated that a hand receives 150 weeks of indemnity in accordance with the legal stipulation of the industrial law. A hand and wrist is stipulated as 175 weeks.

In order that the hand might continue to receive its full indemnity, whether as a hand alone or in "hand and wrist" disability, its relative value to a hand and wrist must be adjusted accordingly. Therefore, it is found that the hand, in this instance, must be given a value of 85.7 per cent of a hand and wrist (150/175 = 85.7%). Leaving off the fraction, 85 per cent is used as the whole number.

This would allow only 15 per cent for the wrist. The wrist when involved alone probably possesses more value than that, and therefore, the wrist value has been placed at 35% of the hand and wrist.

In adding these two values, it is again seen that the total exceeds 100 per cent by too great a margin (85% + 35% = 120%).

It therefore becomes necessary when multiple disabilities are involved to use a formula, wherein the hand unit is divided by one, and the wrist unit divided by two. This would leave the following equation:

$$\frac{85\%}{1} + \frac{35\%}{2} = 102.5\%$$

The excess of 2.5 per cent would be sufficient to allow a slight amount of motion in the hand and wrist and still constitute 100 per cent disability. In figuring a disability of a "hand and wrist" one first figures the disability in the hand as explained in a previous paragraph, then figures the disability of the wrist, and applies these figures to the formula as previously illustrated.

As an example, if we could again assume 50 per cent disability of the hand and 50 per cent disability of the wrist, we would obtain the following equation:

$$\frac{50\% \times 85\%}{1} + \frac{50\% \times 35\%}{2} = 51.2\%$$

It is here revealed that we have been generous to the extent of 1.2 per cent.

Figure 4 illustrates the industrial member of an arm (upper extremity). In this instance it will be noted that the hand and wrist receive different values than they received when evaluated on the basis of a "hand and wrist."

I shall again point out that a hand must receive an indemnity of 150 weeks, whether on the basis of a hand alone, on the basis of a "hand and wrist," or on the basis of an entire upper extremity. In that an entire upper extremity receives an indemnity value of 200 weeks, the relative value of the hand in this instance would be 75 per cent (150/200 = 75%). Likewise a "hand

and wrist" which receives an indemnity value of 175 weeks must continue to receive 175 weeks even though the disability must be based on the entire upper extremity (175/200 = 87.5%). Therefore, in this instance, the wrist value must then be placed at 26 per cent.

Applying these two figures to the formula reveals the following:

$$\frac{75\%}{1} + \frac{26\%}{2} = 88\%$$

This represents one-half of 1 per cent in excess of the legal relative value (88% × 200 weeks = 176 weeks). This represents one week in excess of the 175 weeks of specified indemnity. This seems to be accurate enough and is as accurate as can be obtained without using fractions.

Figure 4 illustrates that the elbow receives a value of 60 per cent and the shoulder a value of 55 per cent. Using the formula, to calculate the disability in the upper extremity wherein all the joints are involved, the following is obtained:

$$\frac{75}{1} + \frac{26}{2} + \frac{60}{3} + \frac{55}{4} = 121.7\%$$

The 21 per cent excess would allow approximately 15 degrees of motion in every joint of the upper extremity and still constitute 100 per cent. An upper extremity with no more motion than that would be industrially useless.

The above figures and description show my method of calculating disability in the upper extremity. Similar figures and similar methods have been used for the lower extremity. More details with regard to the origin of these figures and the method of arriving at this method of calculating disabilities will be explained in a subsequent publication.

Discussion

Dr. George Dunn: Doctor Rice has presented a very interesting paper. He has obviously given this matter a great deal of study.

In estimating permanent disability, one must remember that the estimate furnished by the doctor must harmonize with the existing laws of that particular state, otherwise the estimate becomes worthless.

Doctor Rice emphasized the importance in his general considerations of estimating disability largely on objective findings. This, in my opinion, is a very important consideration.

I enjoyed the paper very much and it will be very interesting after this paper has been published to study it carefully.

Dr. R. E. Hultkrans: I would like to make reference to two articles by Doctor Dunn about estimation of disabilities which appeared in Minnesota Medicine, and also one by Doctor Henry and Doctor Evans on "Interpretation of Disability in Minor Joints in Total Disabilities of the Extremities."

Doctor Rice has done an excellent job in calculating this so well. I think that any attempt to simplify this thing is extremely difficult, but I would like to call attention to the articles on estimation of disabilities previously published by members of this society, which will fall in line with what Doctor Rice has said tonight.

Dr. Earl C. Henrikson: I am not sure that I understood whether the subject of your paper is on the estimation of joint disability alone. Should the calculation of permanent disability be restricted to the estimation of joint action only? If the estimation is on the joints alone the question comes up as to the additional disability due to sensory disturbances as well as other changes. I do not think you mentioned anything in your paper other than joint disability.

Dr. Rice: I mentioned briefly only a few of the factors that had to be estimated. Loss of motion is the greatest factor in the cause of disability. I, therefore, dealt with only this one factor at this time. There are many other minor factors which contribute to a disability. These will be discussed later in a more detailed publication.

Many of those factors are pretty much of a guess. A certain number of them can be fairly well estimated and I think I have devised a method for some of them. If the radial nerve has been severed in the area above the elbow, all power of extension of the wrist and fingers have been lost, and the individual possesses no range of motion in the wrist or fingers. He would, therefore, retain 100 per cent disability of the hand and wrist. Other nerves transmit motor power to certain muscles, the loss of which would in turn produce loss of motion in the joints supplied by such muscles. These lost motions can be measured, and the disability thereby calculated.

Loss of sensation to an important tactile area such as the distal ends of the fingers constitutes from 10 to 15 per cent loss to the distal phalanx. If the distal phalanx has a value of 50 per cent of the finger, the loss to the finger would then be from 5 to 10 per cent of the finger.

Loss of sensation to skin over a small portion of the arm or forearm offers no industrial disability, and should therefore be worth no compensation award.

Loss of strength in co-ordination, instability, deformity, et cetera, has some value, but most of these are manifested by loss of the use of a member or a part of the member. I maintain that the useful range of motion should be used as a criterion. I do not ask an individual to force his range of motion. I merely encourage him to demonstrate his useful range of motion, using that as the criterion for my calculations. In so doing, I have taken into consideration most of the other factors such as weakness, pain, instability, inco-ordination, et cetera, and see no need to add additional values for these.

Dr. R. F. McGandy: I am very much interested in seeing this published. I would like to read it more carefully.

Do you compare one member with the other in arriving at a disability?

Dr. Rice: Yes, surely. All of the measurements are calculated against the opposite normal. In calculating specific disability, the opposite normal is used just as has been explained with the lantern slide illustrations.

Dr. McGandy: In the wrist you mentioned flexion and extension only and didn't take radial and ulnar deviation into consideration.

Dr. Rice: Ordinarily you need not. If the patient has lost all of a major motion, that is all you need take into consideration. Under such circumstances, minor motions would have no industrial value. To give them value when the major motion is completely lost would deprive the injured individual of disability due him.

If dorsi flexion, plantar flexion, ulnar deviation, and radial deviation were divided and each given equal values, their totals could not exceed 100 per cent. Then if each of these were found to have lost 50 per cent of their individual motions, the disability to the joint would still be 50 per cent. Most joints when developing a limitation of motion, develop it essentially equally in all of its various areas. It is, therefore, necessary only to calculate on the basis of one of the arcs of motion, i. e., dorsi-plantar flexion (the major arcs).

Minnesota Academy of Medicine

Meeting of November 14, 1945

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 14, 1945. Dinner was served at 7 o'clock and the meeting was called to order by the President, Dr. A. G. Schulze, at 8:05.

There were forty-five members and six guests present. Minutes of the October meeting were read and approved.

Dr. Erling Hansen read the following Memorial to Dr. Horace Newhart, and a motion was carried that this be spread on the minutes of the Academy and a copy sent to Dr. Newhart's family.

HORACE NEWHART

1872-1945

Dr. Newhart was born in New Ulm, Minnesota, on December 9, 1872. His preliminary education was received there and at Carleton College at Northfield, Minnesota. His Bachelor's degree was received from Dartmouth, where his scholarship was won him the Phi Beta Kappa key. From Hanover, he went to the University of Michigan for his medical course.

After a short time in practice near Albany, where he married Anne Hendrick, he returned to Minnesota and settled in Minneapolis for general practice in 1901.

Later, he decided to specialize in diseases of the eye, ear, nose and throat and spent several years in Vienna under Neumann, Hayek, Rutin, Alexander, and others, who became his close personal friends. Dr. and Mrs. Newhart were in Europe at the outbreak of World War I, and have returned there several times for visits. Several of the Viennese faculty have from time to time been guests in their home in Minneapolis.

Dr. Newhart was on the faculty of the University of Minnesota Medical School since 1912, and for several years before his retirement from active teaching in 1941 was director of the Division of Otolaryngology. His chief interest was always in otology.

Since the early '20's, Dr. Newhart has been a champion in the field of prevention of deafness and conservation of hearing, together with the problems of those who have become hard of hearing. His almost fanatical zeal in this field will long be remembered by those who came in contact with him.

This zeal bore fruit in his home community and in many distant places in the establishment of routine hearing tests for school children, the improvement in audiometers for testing hearing, and the development of better hearing aids. For many years he was chairman of the committee of the American Academy of Ophthalmology and Otolaryngology which dealt with conservation of hearing. He was co-author of the manual which the Academy issued on hearing tests only a few days before his death. He served the Academy as its President in 1925. He was made an active member of the Minnesota Academy of Medicine in 1931.

In addition to the activities already mentioned, Dr. Newhart was a member of his local and state medical societies and the American Medical Association, the Minneapolis Society for the Hard of Hearing, which he organized and of which he was president from 1925 to 1929; the American Society for the Hard of Hearing, president 1927-1928; American Laryngological, Rhinological and Otological Society; the American Otological Society, president 1939-1940; American College of Surgeons; American Acoustical Society; The Minnesota Academy of Ophthalmology and Otolaryngology. He belonged to Sigma Chi and Phi Rho Sigma fraternities and to the Lafayette, Minikahda and Campus Clubs. His hospital connections were with University, Northwestern, Abbott and St. Barnabas hospitals in Minneapolis and Glen Lake Sanatorium.

Dr. Newhart died at Northwestern Hospital on July 9, 1945, after a short illness. Funeral services were conducted Thursday, July 12 at Lakewood Cemetery Chapel with Dr. Donald J. Cowling, president of Carleton College, conducting the services. He is survived by his wife, Anne Hendrick Newhart; a son, Ellwood H.; a sister, Grace, and two grandchildren, Anne and Sally.

The Executive Committee and members present approved Dr. Thomas Robert's request that his name be transferred from the Active to the Senior Membership list.

Upon ballot, the following men were elected to membership:

St. Paul.—Dr. Wallace Ritchie and Dr. Joseph Borg; *Minneapolis.*—Dr. L. R. Boies, Dr. E. F. Robb, and Dr. H. B. Hannah.

The scientific program followed.

SEROLOGY AND OBSTETRICS

RAE T. LA VAKE, M.D.

Minneapolis, Minnesota

Dr. La Vake's paper appears in this issue, page 130.

Discussion

Dr. Lee Barry, Saint Paul: Karl Landsteiner, in 1900 and 1901, grouped human blood into four groups. Because of the cumbersome methods of blood transfusion, blood grouping had more of an academic than a practical interest until after 1911. Landsteiner and Wiener, in 1940, found that 85 per cent of human individuals contained a factor in their blood which was called the Rh factor. Levine, in 1941, established the role of the Rh factor as the cause of erythroblastosis foetalis.

Dr. La Vake, in his paper, states that the A, B (basis of blood grouping) and Rh antigens are more than agglutinogens. They at times may act as toxins. This is especially true when the fetus possesses one or more of these toxins or antigens and the mother does not. He is of the opinion that a toxin-antitoxin reaction between the mother and child due to difference in blood factors is the cause of erythroblastosis foetalis, pre-eclamptic toxemia, eclampsia and premature separation of the placenta.

Dr. La Vake, closing: This paper merely purports to lay before you certain conclusions to be drawn from a concomitant study of serology and obstetrics. If these conclusions are true, they should give direction to our therapy of pregnancy toxemia. The question has presented itself, that if we assume that the lesions of pregnancy toxemia are due to a fetal toxin, which stimulates the production of an antitoxin in the mothers, an antitoxin that may injure or kill the fetus, may it not reasonably be assumed, that, as the lesions of toxemia pregnancy may be permanent and life shortening for the mother, so the lesions of the antitoxin may be permanent for the fetus, even though by blood transfusions we may ostensibly clear up the visible signs of the injuries and save the immediate life of the child. Experiments are now under way that may aid in settling this question. As you all know, snake venom is merely a concentrated saliva. Eighty per cent of humans are secretors, having the hereditary ability to secrete their antigens in the saliva. This is apparently a phylogenetic carry-over. This may explan the sinister appearance and actions of many human bites. If the toxin antitoxin relationship between fetus and mother accounts for pregnancy toxemia and erythroblastosis and allied fetal injury, it would suggest itself that, could a rattlesnake be attached to its host as a child is attached to its mother, the snake could be injured and killed *in situ* by the administration of appropriate antitoxin to the host. The attempt is being made to so injure young rattlesnakes by direct injection of antivenom, to see if permanent injury results if the attack is protracted over a long span of time and to the point of death under conditions analogous to those obtaining in severe cases of erythroblastosis. The results of this work will be reported to you later. It is important because though our responsibility is clear in attempting to cure erythroblastosis by transfusion after delivery, it is not clear that we are warranted in subjecting a woman to the increased risk of cesarean section if permanent and inhuman results are likely to obtain in the fetus, even though the immediate life of the fetus can be saved by transfusion.

PREGNANCY COMPLICATED BY IDIOPATHIC THROMBOCYTOPENIC PURPURA AND SARCOID DISEASE OF THE SPLEEN; SPLENECTOMY AND SUBSEQUENT NORMAL DELIVERY

Case Report

MARTIN NORDLAND, M.D., R. S. YLVISAKER, M.D. (by invitation), PAUL LARSON, M.D. (by invitation), and ROBERT REIFF, M.D. (by invitation)
Minneapolis, Minnesota

Dr. Martin Nordland, Minneapolis: The occurrence of purpurahemorrhagica in association with pregnancy may be a coincidence of two unrelated conditions. When it occurs, it is a serious matter. The majority of patients die and the infants seldom survive. In this case the spleen was removed after the pregnancy had progressed for five months and the patient later went through a full term normal delivery. This case report is presented because it was thought it might be of interest to this group and because of its rarity we wished to place the report on record.

Too much praise cannot be given to the internist in the management of this case. The preparation of the patient and the choice of the time of the operation are of paramount importance in the successful removal of the spleen, under these circumstances. In order that the report may be presented to you in an orderly fashion, I shall ask Dr. Ylvisaker to give you the history, together with his comment. Dr. Reiff will discuss the hematology, and Dr. Larson will present the problems concerned with the obstetrical delivery. After they have finished, I would like to discuss the problems related to the splenectomy as a therapeutic measure.

Dr. R. S. Ylvisaker, Minneapolis (by invitation): The case presented tonight is that of a twenty-six year-old white housewife, (N. P.) who was first admitted to Northwestern Hospital October 28, 1943, and discharged November 10, 1943.

Present Complaint: (1) Multiple petechiae and acchymoses; (2) profuse menstruation.

Present Illness: Her illness began about six weeks before admission when she first noted "red spots" over the lower extremities and abdomen. After three or four days, larger areas appeared over the ankles, followed by many such over the legs, hips and arms. Her menstruation two weeks prior to admission was very profuse and she felt faint if she tried to be on her feet. It was of normal duration. She struck her breast in a fall shortly before admission and a large ecchymotic area developed at the site of injury.

Family History: Both parents are living and well; divorced; there are no brothers or sisters and the family history is otherwise non-contributory.

Past History: She had a severe diphtheria at one year of age, complicated by an abscess which developed at the site of injection of antitoxin. There had been measles at the age of six or seven. A tuberculous chest lesion was said to have been found at the age of eight, for which she had been kept out of school for one year. She had been under observation at Lymanhurst Clinic, Minneapolis, from that time until 1942. The Clinic records revealed that an x-ray of the chest taken in 1926 at the age of nine, showed slight enlargement and calcification of the hilus glands in both lungs and clear lung fields. There was no Mantoux test done at that time, but in 1931, at the age of 13, the 1:1000 Mantoux was negative, the 1:100 was 1 plus positive. In 1942, 1-1000 Mantoux was again negative.

She had been hospitalized for two weeks at the age of ten for acute pyelitis with complete recovery. There had never been a recurrence. She had had jaundice for two or three weeks at the age of fourteen. There was no bleeding tendency then. She had been confined to bed, also at the age of fourteen, for a supposed heart disorder for a period of six months, but was later told there was no heart disorder. She was hospitalized December 28, 1941, with first and second degree burns and aborted shortly after this, with no excessive bleeding. No history could be obtained of any symptoms suggesting any allergic disorder and there had been no ingestion of drugs. She has one healthy child, three years of age.

Physical examination on admission was normal except for the presence of numerous petechial hemorrhages scattered over the lower extremities and a smaller number over the upper extremities and trunk, as well as several old and recent ecchymoses over the right breast, both hips, both legs and both arms. The spleen at first could not be palpated, but on the third day it was felt just below the costal margin. The blood pressure was 120/78.

Laboratory Findings: Blood: hemoglobin 13.2 grams, red cells 4,590,000, white blood cells 7,600; differential: p.m.n.'s 67 per cent, lymphos. 23 per cent, monos. 8 per cent, eos. 1 per cent, baso. 1 per cent. Bleeding time 2½minutes, clotting time 5 minutes 20 seconds. Platelet count 60,000 per c.mm. Prothrombin time 6'/4'35". Later platelet counts, 108,000 and 112,000. On the eleventh day the hemoglobin was 16.8 grams, white count 10,900.

The patient was given two transfusions of 500 c.c. each of citrated blood. This apparently completely controlled the purpura and a menstrual period during her hospital stay was normal except for slightly increased flow the first day.

She was readmitted to the hospital October 26, 1944, discharged November 8, 1944. She was now five months pregnant. She stated that she had been well until a few days previously when the purpura had recurred. Examination again revealed numerous petechiae and ecchymoses over the entire body, but most numerous in the lower extremities. The spleen was palpable. There was a bloody crust in the right nostril.

Laboratory Data: Hemoglobin 12.0 grams, red cell count 4,380,000; white count 10,400; platelets 110,000; later 140,000, 180,000, and 250,000. Bleeding time 2 minutes 25 seconds, clotting time 4 minutes 50 seconds. Clot retraction began in 4½ to 5 hours and was still incomplete in 24 hours.

She was given five transfusions of citrated blood during this admission with incomplete control of her purpura.

Her third admission to the hospital occurred on November 12, 1944, four days after her previous discharge. There had again been exacerbation of the purpura over the entire body, in the conjunctivae, and over the dorsum of the tongue. She had noted frankly bloody urine three days previously. The spleen was palpable. The fundus of the uterus was at the level of the umbilicus. The Mantoux test was negative with 1:1000 tuberculin.

Laboratory Data: Hemoglobin 13.5 grams, red cells 5,250,000, white count 11,800; p.m.n.'s 78 per cent, lymphos. 17 per cent, monos. 4 per cent, eos. 1 per cent. Bleeding time 40 minutes, clotting time 3 minutes 20 seconds. Ivy bleeding time 54 minutes; platelet counts ranged between 80,000 and 230,000. Cuff test was positive. Prothrombin time 20'/15'. Clot retraction was incomplete in 24 hours. Sternal puncture was done by Dr. R. Reiff and he reported a marked megakaryocytic hyperplasia. He stated that smear of the peripheral blood showed less than 25,000 platelets and they were distinctly abnormal in appearance.

She was given a total of seven transfusions of 250 to 500 c.c. of citrated blood with incomplete control of the purpura. It was, therefore, deemed unwise to allow her to go to term without more drastic measures to control her bleeding tendency. Moreover, it was felt that all the diagnostic criteria of a true, idiopathic thrombocytopenic purpura had been fulfilled. Splenectomy was therefore advised and was done November 21, 1944, by Dr. Martin Nordland. During the operation it was noted that bleeding stopped as soon as ligation of the pedicle was completed.

Pathological examination of the removed spleen revealed the presence of sarcoid disease. Postoperative convalescence was uneventful except for the devlopment of a partial atelectasis of the lower lobe of the left lung which cleared without further difficulty. X-rays of the lungs and the bones of the hands revealed no evidence of sarcoid disease and no skin lesions were observed at any time. She was discharged on the fourteenth postoperative day in good condition. No further purpura was noted.

Her last admission to the hospital occurred March 23, 1945, at which time she was delivered spontaneously of a normal infant without incident. The puerperium was normal.

Further details of the hematological and pathological aspects of this case will be discussed by Dr. Robert Reiff, obstetrical aspects by Dr. Paul Larson, and the surgical aspects by Dr. Martin Nordland.

I shall not burden you with any lengthy discourse on this disease, but it might be of value to review, briefly, the main landmarks in the development of our present concept of idiopathic thrombocytopenic purpura.

Werlhof first described essential purpura in 1775. This was an acute case in a ten-year-old child which recovered spontaneously.

Donne, 1842, was supposed to have originally described platelets (globulins).

Denys was the first to show a reduction of circulating platelets in Werlhof's purpura in 1887.

Hayem discovered poor clot retraction in 1896.

Wright, 1910, demonstrated that platelets arose from megakaryocytes in the bone marrow.

Duke, 1911, showed that clotting time was normal, but that bleeding time was increased.

Frank, 1915, first enunciated the theory that thrombocytopenia was due to a megakaryocyte maturation defect.

Kaznalson, 1916, theorized that there was an increased platelet destruction presumably in the spleen, and suggested the first splenectomy which was done for thrombocytopenic purpura.

Marrow biopsy was first introduced by Seyforth, 1923, and was simplified by Arinkin in 1929.

Limarzi and Schleicher, 1940, summarized our present concept of the role of the megakaryocyte in thrombocytopenic purpura and described the bone marrow picure.

Schwartz, 1945, showed the presence of high eosinophile counts in the marrow in allergic purpuras and low counts in essential thrombocytopenic purpura and commented on the prognostic significance.

As far as the association of purpura and pregnancy is concerned, apparently some type of purpura was first observed in pregnancy by Arand in 1765, but it was not until a century later that Barnes reported what is commonly considered the first case of true purpura in pregnancy. From that time on, scattered cases were reported until, in 1943, Burnett and Klass could find only sixty-eight cases in the literature. Forty of these they considered doubtful cases, eighteen symptomatic and only four true cases of thrombocytopenic purpura. They added one of their own.

Finn, 1944, found five other cases which he considered true thrombocytopenic purpura and added three cases from the New York Hospital records. He found only four cases in which splenectomy was done during pregnancy for the purpura: (1) case of Palowe, 1940; (2) case of Bernstein, Newman and Hitzig, 1939; (3) case of Phythyon and Lartz, 1943; and (4) case reported in a letter in the *Journal of the American Medical Association*, written by Grommen, referring to a splenectomy done by Garlock.

A uniformly high mortality rate in both mothers and infants when splenectomy is not done, is reported by all writers—usually 55 per cent to 60 per cent. Rushmore, 1925, reported that of forty-four mothers, twenty-six died, and of forty-two babies, twenty-seven died, seven of the fifteen infants showing evidence of purpura.

As far as we know, the case being reported tonight is the fifth case to be reported in which splenectomy has been undertaken during pregnancy. Undoubtedly there have been other cases which have not been reported. We have been informed of a case in which operation was performed at the Minneapolis General Hospital at about the same time as this case and in which the mother later was delivered normally of a normal infant.

Features of the disease during pregnancy probably do not differ from those in the nonpregnant state. However, Evans and Perry, 1943, reported a case in which striking improvement occurred during pregnancy with a rise in platelets to 770,000, and a normal bleeding time. In this case, there was a reappearance of symptoms and a fall in platelets after delivery. They commented on the difference in incidence of the disease in males and females and suggested an endocrine etiology of the disease. In all likelihood their patient was sensitive to some estrogenic substance.

The relationship of purpura hemorrhagica to sarcoid disease of the spleen is not certain. In the light of cases of purpura which have been reported, secondary to cirrhosis and other liver diseases, tuberculosis of the spleen and other infections, our case should probably be classified as secondary to the sarcoidosis of the spleen. The only other case of purpura hemorrhagica which we have been able to find reported as secondary to sarcoid disease of the spleen, was by Schwartz, 1945, who stated that sarcoid disease of the spleen was present in one of his thirty cases.

* * *

ROBERT H. REIFF, Ph.D., University of Minnesota (by invitation): The day preceding splenectomy, the significant hematologic findings were as follows: peripheral blood smears were essentially negative except for a severe thrombocytopenia—platelets numbered less than 20,000 per cubic millimeter. Sternal puncture revealed a moderate neutrophilic hyperplasia and an enormous increase in both the relative and absolute number of megakaryocytes. These cells numbered 1,822 in the terminal 18 square millimeters of the smears (normal—approximately 56). Megakaryocyte morphology was normal except for the absence of granular zoning characteristic of platelet formation in the adult cells. Very few platelets were found in the marrow smears. The bleeding time was 50 minutes, clotting and prothrombin times were normal, the clot did not retract, and the cuff test was markedly positive. The spleen was palpable but not remarkably enlarged.

Six days postoperatively, the platelet count had risen to 484,000; it ranged between 440,000 and 500,000 during the next four days. Three months later, the count was 464,000.

The spleen weighed 275 grams. The capsule was smooth, and the follicles were visible on the cut surface. Microscopically, many of the Malpighian bodies were replaced by tubercles composed of epithelioid cells and containing giant cells of the Langhans type. The lesions differed from those of tuberculosis only in the absence of necrosis in the central portions. The pulp showed no changes. The pattern was interpreted as typical of Boeck's sacroid.

Platelet counts, even in the most experienced hands, are often inaccurate and should always be checked by a study of the stained smear as well as the retractility of the clot. Bone marrow biopsy serves a manifold purpose. First, it excludes many of the causes of symptomatic or secondary purpura such as aplastic anemia, aleukemic leukemia and other lympoblastomas, extensive carcinomatosis, lipoid storage diseases, and others. Second, it affords a method of obtaining a quantitative as well as qualitative estimate of the megakaryocytes.

As J. H. Wright demonstrated in 1906, it is through the fragmentation of the cytoplasm of the megakaryocytes that the blood platelets are formed. Limarzi and Schleicher first called attention to the marked increase in the number of megakaryocytes in the bone marrow in essential thrombocytopenic purpura. In the cases which we have had an opportunity to study, the megakaryocytes ranged from eleven to sixty times the normal number prior to splenectomy. In each of these cases, removal of the spleen was followed by a prompt rise in the number of circulating platelets and concomitant disappearance of abnormal bleeding. Since the oldest case in our series was operated less than four years ago, information regarding late recurrences is not available.

In two cases, bone marrow biopsy revealed, in one, a marked decrease and, in the other, a complete absence of megakaryocytes. The spleen was removed in both cases because of progressively profuse hemorrhage in the presence of conservative therapy. Both continued to bleed postoperatively with a fatal outcome.

The presence of a palpable spleen suggests a complication; in this case, sarcoidosis. The literature is in fair agreement that the spleen is not enlarged in uncomplicated essential thrombocytopenic purpura. It is interesting to note, in connection with the case under discussion, that tuberculosis of the spleen has been found in rare instances of thrombocytopenic purpura.

The occurrence of thrombocytopenia in some newborn infants of mothers with purpura (Wintrobe), the marked decrease of marrow platelets in the presence of abundant megakaryocytes, and the usual absence of splenic pathology would appear to support Frank's original hyopthesis that the mechanism responsible for the thrombocytopenia is to be found in a failure of the megakaryocytes to form platelets, rather than in splenic sequestration and destruction.

* * *

Dr. Paul Larson, Minneapolis (by invitation): The essential points in diagnosis, treatment, etc., of the blood disease have been well covered by the hematologist, internist and surgeon. I shall only outline the prospects of the mother and child as well as describe the uneventful outcome of a successful case, in which sarcoid also was present.

To date, thirteen cases constitute the total number of reported cases of thrombocytopenic purpura complicating pregnancy. Of these, only three have had splenectomies during pregnancy, while three others had the same operation before gestation. One other had her splenectomy the seventh day postpartum because of severe postpartum hemorrhage. This last case is the only death in the group and, curiously enough, the only one in which severe postpartum bleeding occurred. Undoubtedly more cases would come into this category as the statements of Bernstein, Newman, Hitzig, Phythyon, Lartz, and Grossman bear out, but no reports are found.

Because of the rarity of this complication of pregnancy, little is known. There apparently exists no causal relationship between this type of purpura and pregnancy. It is a coincidental complication. It may occur at any parity, although those reported were all multipara except two. It may occur at any time during gestation. While it may be true that all cases of purpura will eventually die of hemorrhage, strangely enough, only one of the entire group reported developed a severe postpartum hemorrhage.

Outcome of the Baby.—Here a great variance of opinion exists, but from these reported cases in the literature the following points are evident:

1. Five infants died, one of which had proven thrombocytopenic purpura. The other four died of prematurity or atelectasis.
2. Seven normal children were born, and
3. One bled until the seventh day, then cleared.

It is evident that if complete remission of the process occurs after splenectomy, the newborn more likely will not be affected. It is believed that this purpura may be congenital but not necessarily inherited. It is difficult to draw any conclusions from such a small group of cases but it would appear that the newborn has a better chance if splenectomy has been done prior to the pregnancy or if the disease is in a chronic phase as pointed out in Finn's article.

Case Report.—Mrs. N. P., aged twenty-seven, grav. 3, para. 1, married five and one-half years. Her first pregnancy terminated at term uneventfully and resulted in the birth of a child in good health (1940) weighing 8 pounds 4 ounces. She had a miscarriage in 1941 at two months' gestation following a severe burn. In 1943 she developed petechiae in the arms and legs during which time she also developed a profuse menstrual period which was unusual for her. At this time a diagnosis of thrombocytopenic purpura had been made after adequate study. Her last menstrual period was June 6, 1944. There was a moderate amount of nausea the first trimester, with the pregnancy continued uneventfully until October 26, 1944, when she was admitted to Northwestern Hospital with a repeat episode of petechiae on the arms and legs. Several transfusions were given and she was discharged November 8, 1944. The patient returned again November 12, 1944, with a recurrence of the petechiae plus gross hematuria. After proper preparation, the patient had a splenectomy November 21, 1944, following which she recovered uneventfully. The pregnancy then continued without incident until labor was induced with castor oil and crude extract of ergot on March 24, 1945, at full term. Labor was five hours, normal, and no excessive bleeding followed. Delivery of a 7-pound female infant was spontaneous. The puerperium was normal.

The details of the blood studies during this time have been covered thoroughly by the internist.

Dr. Nordland: In the acute phases of purpura hemorrhagica, the natural tendency is toward improvement. This makes it difficult to evaluate any therapeutic measure, without due regard to the natural course of the disease, whether treatment is administered by conservative methods or by splenectomy. Because the course of purpura hemorrhagica is varied, caution must be exercised in becoming overenthusiastic for splenectomy. Evaluation of the effects of operation as compared with the course of the disease in unoperated cases must be made only after the lapse of many years. There can be no question that splenectomy is a very valuable procedure in suitably selected cases. As was noted in this case, many surgeons have described total cessation of bleeding as soon as the splenic pedicle was tied. Surgical mortality should not exceed 5 per cent. Of these, no doubt, some would have died even if splenectomy had not been done. Removal of the spleen should not be done during an acute phase. Transfusions are extremely valuable preceding splenectomy. Frequent small blood transfusions of 100 to 300 c.c. given at intervals of two to three days have been considered of most value.

The indications for splenectomy may be enumerated as follows:

1. If bleeding is severe and fails to subside after repeated transfusions, splenectomy should be seriously considered. If there is any suggestion of improvement, however, operation should be deferred. Splenectomy is safer in the quiescent stage. In the first episode of bleeding, especially in children, it is more probable that bleeding will subside spontaneously rather than become more severe.
2. Operation should be given greater consideration in females than in males because of the possibility of a serious episode at menstruation or during pregnancy, as well as because recurrences seem to be more common in females than in males (4 to 3).
3. In chronic or recurrent cases, in addition to the above considerations, splenectomy is advisable if growth or development or the social or economic status of the patient is seriously impaired by recurrences, even if the hemorrhage is only moderate in character.

Splenectomy is contra-indicated in:

1. Cases of doubtful diagnosis,
2. Cases of symptomatic or secondary purpura such as those associated with acute infections or caused by some drug.

The removal of the spleen is not considered a particularly difficult operation. It is well to note, however, that because of its high location in the abdomen, the approach is occasionally difficult. This is particularly true in a woman well advanced in pregnancy. Anatomically, it is well to remember that the blood supply of the spleen is very abundant. The splenic artery, next to the renal artery, is the largest vessel supplying any abdominal viscera and is all out of proportion to the organ itself. The splenic artery, coming from the celiac axis, divides itself into a series of branching networks, finally allowing blood to percolate through the interstices of reticulo-endothelial tissue. Therefore, the spleen should be thought of as an organ made up of blood vessels and a fracture of this organ should be considered as a tear in one of the most vascular tissues in the body.

Discussion

Dr. S. E. Sweitzer, Minneapolis: This case to me is interesting from the fact that this woman had sarcoid of the spleen. Sarcoid was first described by Boeck in 1889 as a cutaneous disease and later it was divided into several manifestations. Later, Schaumann called sarcoid lymphogranulomatosis maligna. It may involve the tonsils, bones, lungs, and nodes, and there are also skin manifestations.

Snapper and Pompeu in 1938 reported 13 cases. The lungs were involved in 8 cases, 5 had skeletal involvement, 5 had ocular involvement, the spleen was involved 7 times, 7 had cutaneous involvement, and 4 had liver involvement.

This patient, possibly on her symptoms, may have had primary sarcoid in the spleen; if so, she had a rare type of sarcoid. I do not remember seeing any individuals with sarcoid who had cutaneous hemorrhages.

The meeting adjourned.

J. A. Lepak, M.D., *Secretary.*

SEROLOGY AND OBSTETRICS

(Continued from Page 132)

An understanding of the toxin-antitoxin relationship suggests the proper direction of studied therapy in the toxemias of pregnancy, erythroblastosis fetalis and in delayed transfusion toxemia.

Rh similar blood should be used in transfusion to prevent possible disaster if the woman has been isoimmunized by pregnancy or transfusion and to prevent isoimmunization that may interfere with her future ability to bear viable children.

CALCULATION OF DISABILITY IN THE EXTREMITIES

(Continued from Page 164)

Dr. McGandy: How do you figure pronation and supination in estimating a disability on a wrist?

Dr. Rice: Pronation and supination of the forearm may come into disability estimation either in the elbow or in the wrist, depending upon from which it originates. If pronation and supination are completely lost, half of the wrist or elbow motion is lost. Dorsi-palmar flexion represents half of the motion in the wrist, and flexion-extension represents the other half of elbow motion.

Dr. McGandy: I noticed that in your method of estimating a shoulder disability, you only mentioned forward elevation and backward elevation, saying nothing about internal and external rotation or lateral elevation.

Dr. Rice: Ordinarily when one motion in the shoulder is lost, the other motions have a comparable loss. It would be extremely rare to retain all of forward-backward elevation, and lose only abduction-adduction. In normal activity, one does not use only one of the shoulder motions at a time. All three of the motions are being constantly and synchronously used.

ANNUAL PRIZE CONTEST

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons Foundation announces that the annual prize contest will be conducted again this year.

For information address Dr. James R. Bloss, Secretary, 418 11th Street, Huntington 1, W. Va.

AMERICAN UROLOGICAL ASSOCIATION AWARD

The American Urological Association offers an annual award "not to exceed $500" for an essay (or essays) on the result of some specific clinical or laboratory research in Urology. The amount of the prize is based on the merits of the work presented, and if the Committee on Scientific Research deem none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. All interested should write the Secretary, for full particulars.

The selected essay (or essays) will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Netherland Plaza, Cincinnati, Ohio, July 22-25, 1946.

Essays must be in the hands of the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tennessee, on or before July 1, 1946.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION AWARD CONTEST

The National Gastroenterological Association announces the establishment of an Annual Cash Prize Award of $100 and a Certificate of Merit for the best unpublished contribution on Gastroenterology or allied subjects. Certificates will also be awarded those physicians whose contributions are deemed worthy.

Contestants residing in the United States must be members of the American Medical Association. Those residing in foreign countries must be members of a similar organization in their own country. The winning contribution will be selected by a board of impartial judges and the award is to be made at the Annual Convention Banquet of the National Gastroenterological Association to be held at the Hotel Pennsylvania in New York City on Thursday evening, June 20, 1946.

All entries for the 1946 prize should be limited to 5,000 words, should be typewritten in English, prepared in manuscript form, submitted in five copies, accompanied by an entry letter, and must be received not later than May 1, 1946. Entries should be addressed to the National Gastroenterological Association, 1819 Broadway, New York 23, N. Y.

AMERICAN COLLEGE OF SURGEONS

The first of the series of ten sectional meetings sponsored by the American College of Surgeons was held at the Hotel Radisson in Minneapolis on January 28 and 29, with surgeons attending from Minnesota, Wisconsin, North and South Dakota, Iowa, Nebraska, Saskatchewan and Manitoba.

Lectures at the opening session were "Treatment of Infection by Chemotherapy and Antibiotics" and "Injuries to the Bile Ducts." During luncheon "Care of the Veteran" was the subject discussed, and dinner was followed by a forum on "Graduate Training in Surgery."

Dr. James M. Hayes, assistant professor of surgery at the University of Minnesota, who was in charge of arrangements, conducted a clinical conference at the January 29 session.

The meetings on both days opened at 8:30 A.M. with medical motion pictures.

MAYO PROFESSORSHIP IN PUBLIC HEALTH

The first permanently endowed professorship in the University of Minnesota was recently created as the Mayo Professorship in Public Health when the Board of Regents accepted endowment of that chair by the

Mayo Properties Association. To pay the salary, which will not exceed $10,000, a gift of $150,000 was made to the University by the Mayo Properties Association, which specified that over and above the income from that sum the total will be made up from the income of the Mayo Foundation for Medical Education and Research.

The School of Public Health was created in the Medical School about two years ago when Dean Diehl recommended that the then department of preventive medicine and public health become a school within the medical school, like the school of nursing. Dr. Gaylord Anderson has been head of the school from the first, although during the war he has been on leave as head of the division of medical intelligence in the office of the surgeon general, war department.

The Mayo Properties Association is the organization formed by the late Drs. Charles H. and William J. Mayo and their associates, to hold and manage the assets of the Mayo Clinic. The Mayo Foundation for Medical Education and Research is an educational division of the University of Minnesota on the graduate level. It was first endowed with $2,000,000 in 1917, which sum was subsequently increased by $500,000 in 1934. It carries on a broad program of graduate teaching, maintains laboratories, and will now contribute to the new professorship.

The School of Public Health is one of six regional training centers in this country having as a principal function the training on the graduate level of doctors, engineers and nurses in public health matters to become specialists. For ten years past the school has had federal support of about $15,000 a year. Columbia, Harvard, Yale, Johns Hopkins, and Michigan are other institutions which have such schools.

Before the war there were from ten to fifteen doctors and from ten to fifteen engineers taking graduate work in public health. These programs were given up during the war but the public health nurses, numbering from 125 to 150, were carried through in the usual numbers. There is also a curriculum in public health education. Besides these programs the faculty gives instruction in personal and public health to undergraduates in many fields, including medicine, engineering, education, home economics, nursing and the like.

Minnesota was designated a regular public health training center after the state health officers of the north central group of states expressed a desire to have the federal government take that action.

FREEBORN COUNTY SOCIETY

The annual meeting of the Freeborn County Medical Society was held on January 18 at the Hotel Albert in Albert Lea. Dr. William L. Palmer, veteran Albert Lea physician, was guest of honor at the dinner which preceded the business meeting.

Dr. Leo L. Donovan, vice president during 1945, was elected successor to Dr. Brand A. Leopard, retiring president. Dr. J. Albert Schulz is the new vice president and Dr. Robert Swanson is treasurer. Dr. John Paul Person, of Alden, was re-elected secretary.

RED RIVER VALLEY SOCIETY

The annual dinner meeting and election of officers of the Red River Valley Medical Society was held at the Wayne Hotel in Crookston on December 27. Dr. Orlo K. Behr, of Crookston, is the new president, replacing Dr. John Cameron, of Erskine. Dr. William W. Johnstone, of Thief River Falls, was elected vice president, and Dr. Chester L. Oppegaard, of Crookston, was re-elected secretary-treasurer.

Dr. John F. Norman, of Crookston, addressed the meeting on "The Prepaid Medical Plan," and general discussion of the subject followed.

About twenty members and their wives attended.

WINONA COUNTY SOCIETY

Dr. John Tweedy was elected president of the Winona County Medical Society at the annual dinner meeting held at the Hotel Winona on January 7. Dr. Herbert Heise is the retiring president. Other officers chosen are: Dr. John S. Hamlon, St. Charles, vice president; Dr. Paul Heise, secretary and Dr. Leonard F. Johnston, treasurer.

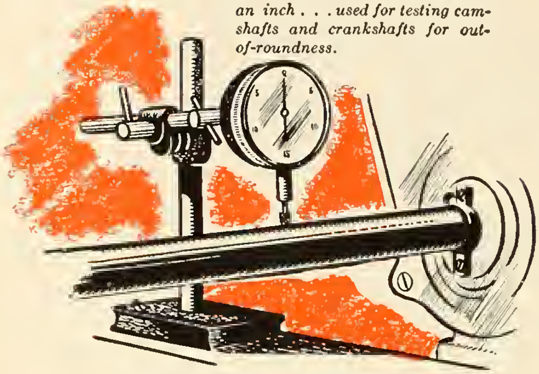
DIAL TEST INDICATOR measuring by half-thousandths of an inch . . . used for testing cam-shafts and crankshafts for out-of-roundness.



WHEN IT'S *Precision*

YOU REQUIRE . . .

FOR the treatment of pernicious anemia, medical science has found a specific in liver therapy.

But like the highly sensitive dial test indicator which measures within .0005 inch, liver extract—to give precise results—must be manufactured with the utmost care.

. . . And nothing less than precision will meet the requirements of the competent physician.

For these requirements, Purified Solution of Liver, Smith-Dorsey, deserves your confidence.

Its uniform purity and potency are traceable to the conditions under which it is produced—to the capably staffed laboratories, the modern facilities, the rigidly standardized testing procedure.

You may be assured of *precision* in liver therapy when you use

PURIFIED SOLUTION OF *Liver*

BLUE EARTH COUNTY

The Blue Earth County Auxiliary members donated to the party given by the Y.W.C.A. at their Club house, December 12, for the Young Mothers' Club and their children. Food and toys were given the children.

EAST CENTRAL

Each Central members elected new officers for the year when they met at the Cambridge Epileptic Colony. Mrs. Gonley was hostess. The new officers are Mrs. E. W. Miller, Anoka; Mrs. R. G. Swenson, North Branch; and Mrs. G. H. Tesch, Elk River.

GOODHUE COUNTY

The Goodhue County Medical Society were hosts to the Auxiliary members at the St. James Hotel, Red Wing, December 10. While the doctors conducted the business meeting, the ladies had a social evening.

HENNEPIN COUNTY

Mesdames H. E. Drill and Frederick Erb were in charge of the Silver Tea at the Medical Arts Building, Minneapolis, December 7. This tea is the annual philanthropic project for Sarahurst, the rehabilitation home for discharged tuberculosis patients. Carol Seagren inspired everyone with the Christmas spirit in the reading of a Christmas play, Julia Denecke, a flutist, added charm to the festive tea.

It's a thrilling record that the Hennepin County Auxiliary has achieved in the Bond booth. The E award has again been granted them; this time, when they had finished their work and exceeded the quota. Special tribute should be paid to the captain, Mrs. H. O. Altman, and to those members who gave unstintingly of their time and effort at the Medical Arts Building booth. Mrs. D. B. Mork points out that it is to their credit that they "stuck to their job and finished in a dignified fashion."

NICOLLET-LE SUEUR

A dinner meeting was followed by a business session at St. Peter on December 10.

RAMSEY COUNTY

One hundred fifty dollars was recently donated by the Ramsey County Auxiliary to the Red Cross Canteen conducted at the Union Depot in Saint Paul. Members continue to make cookies for the soldiers who pass through Saint Paul.

Postural Symptoms During Pregnancy Often Averted Or Relieved By A SPENCER SUPPORT

At left:
A Spencer antepartum support designed especially for this woman. Equally effective for postpartum period.

Abdominal support provides a rest for the weight of the abdomen and is accurately correlated with support to back, thus effecting marked posture improvement.

Light, flexible, easily adjusted to increasing development.

Note, also, the Spencer antepartum-postpartum breast support designed especially for her.

Spencer Supports meet your patients' needs exactly *because*: Each Spencer Support is individually designed, cut, and made at our New Haven Plant *after* a description of the patient's body and posture has been recorded and 15 or more measurements have been taken.

For a dealer in Spencer Supports look in telephone book under Spencer corsetiere, or write direct to us.

RENVILLE COUNTY

It is the custom of the Renville Medical Society to share their distinguished speakers with the Auxiliary members. The doctors arrange the dinner, holding it usually at the county seat, Olivia, and invite their wives. When there is no program, each group conducts separate meetings.

ST. LOUIS COUNTY

The St. Louis County Medical Society Members entertained their wives, December 13, at the annual county dinner meeting held at the Northland Country Club. After dinner, Walter Ridder, columnist, talked on his experiences during the war in the Scandinavian countries.

STEARNS-BENTON

In previous years, Stearns-Benton Auxiliary has given $5.00 to any student from the two counties who was among the ten winners in the state anti-tuberculosis essay contest. This year, since there were no winners from either Stearns or Benton counties, they recognized instead three students who received honorable mention. To stimulate interest in succeeding years, as well as to reward these students for their accomplishment, each was given $2.50 by the Auxiliary. Bernard Schaefer, junior at St. Boniface High School, Cold Spring; Helen Miner, Technical High School, St. Cloud; and Joan Reidar, ninth grade student, at St. Cloud Cathedral were the recipients this year.

WABASHA COUNTY

Wabasha County Auxiliary, just six members and these six members have twenty-three children! Yet they meet regularly and carry on informal discussions on weighty matters, such as *"Essentials for World Peace,"* their December subject. They place *Hygeia* subscriptions not only in the hospitals, offices and libraries, but also in the beauty parlors. They also make cancer dressings. On December 8, they met at the home of Mrs. A. G. Ashner at Wabasha.

WASHINGTON COUNTY

Mrs. J. W. Stuhr was hostess at Stillwater, December 9, for the group of which she is president. Christmas stories were read and gifts sent to two of their members who were sick.

Case finding among symptomatic patients cannot be expected to result in a majority of those patients being discovered at a minimal stage; and contact examination among associates of diagnosed patients, although yielding a high proportion of early cases, is limited in its scope, especially among urban residents. Mass roentgenography would appear to be needed if substantial reduction of cases which are advanced at the time of discovery is to be achieved.—Berwyn F. Mattison, M.D., *Amer. Jour. P. H.*, Nov., 1944.

In Memoriam

JOHN LeROY BURTON

Dr. J. L. Burton, the only physician at Buhl, Minnesota, was killed October 31, 1945, when his car went off the road.

Dr. Burton was born in Stewartville, Minnesota, February 5, 1904. He received his B.A. and M.B. degrees from the University of Minnesota in 1935 and his M.D. in 1936, interning at the Minneapolis General Hospital.

Dr. Burton acted as health officer and school physician at Buhl. He was a member of the St. Louis County Medical Society, the Minnesota State and American Medical Associations.

* * *

JOHN FRANCIS CURTIN

Dr. J. F. Curtin of Minneapolis was born at Lawrence, Massachusetts, October 17, 1889. He died December 25, 1945, at the age of fifty-six.

Dr. Curtin obtained a B.A. degree from Holy Cross in 1911, and an M.D. from Harvard in 1915. He interned at the Hartford Hospital and took postgraduate work at the Eye, Ear and Throat Hospital in New York City in 1919-20. During World War I he was instructor in ear, nose and throat surgery in the Army Medical School at Fort Oglethorpe, Georgia.

Dr. Curtin came to Minneapolis in April, 1920, and specialized in the treatment of ear, nose and throat diseases. He was a member of the Minneapolis Academy of Medicine, the Minnesota Academy of Ophthalmology and Otolaryngology, the American College of Surgeons, the Hennepin County Medical Society, the Minnesota State and American Medical Associations. At the time of his death he was chief of the medical staff of Abbott Hospital.

* * *

ERNEST WESLEY RIMER

Dr. E. W. Rimer died of coronary thrombosis on December 22, 1945, at his home in Breckenridge, Minnesota. Dr. Rimer was born at Grand Junction, Iowa, June 20, 1882.

At the age of eighteen he joined the regular army and as a Sergeant in the 15th U. S. Cavalry saw service in the Philippines under Captain John J. Pershing before the close of the insurrectionary period. He also had the distinction of being the first white teacher on the island of Mindanao.

In 1906 he graduated from Valparaiso University with a degree in pharmacy and a B.A. degree. Two years later he received the M.D. degree from Rush Medical College in Chicago.

Dr. Rimer began practice in Breckenridge in 1912 but joined the colors again June 20, 1917. After training at the Army Medical College in Washington, D. C., he went overseas to England as First Lieutenant and became a Captain in the British Medical Corps. He served in France as surgeon of the Fourth Scottish

Division and is said to have been for a time the only American surgeon in the front line trenches. He took part in the battles of Ypres, Cambrai, the Somme, Paschendale Ridge and Kimmel Hill. On one occasion he suffered from gas and at another time was reported killed. He recovered from a severe shell wound and after the Armistice was sent to Glasgow, Scotland, where he remained for eight months on duty in the Brigade Hospital. In 1919 he received the rank of Major in the British Medical Corps, and upon his return held the rank of Major in the U. S. Army Medical Reserve Corps. He received his discharge from the army at Camp Dix in 1919.

Dr. Rimer was a member of the staff of St. Francis Hospital, division surgeon for the Great Northern and Northern Pacific hospitals and county health officer. He was a member of the Park Region District and County Medical Society, the Minnesota State and American Medical Associations. He was a member and trustee of the local Baptist Church, a member of the Masonic Order, the Knights of Pythias, the Independent Order of Odd Fellows and the Elks. Many years ago he held the office of mayor, but all his outside interests yielded to his devotion to his profession.

Dr. Rimer is survived by his widow, and a daughter, Mrs. M. V. Young of Seattle, Washington.

* * *

JOHN CHANDLER SESSIONS

Dr. J. C. Sessions of Minneapolis was born at Atchison, Kansas, September 21, 1879, and died October 19, 1945, at the age of sixty-six.

He graduated from Central High School in Minneapolis and obtained the degrees of B.A. and M.D. from the University of Illinois in 1902. His internship was served in Cook County Hospital, Chicago, and the Minneapolis General Hospital. He took postgraduate study at the University of Illinois in 1908, and again in 1914.

During World War I Dr. Sessions served with the rank of Lieutenant-Colonel as division surgeon of the LaFayette Division.

He was a former member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations.

He is survived by his widow, a son, Lieutenant John A. Sessions, and a daughter, Suzanne.

* * *

ARTHUR W. SHALEEN

Dr. A. W. Shaleen, a practitioner at Hallock, Minnesota, since 1903, died suddenly of a heart attack January 6, 1946, at his home.

Dr. Shaleen was born at Lindstrom, Minnesota, September 13, 1878. His father came to this country from Sweden in 1855 and served in the Sixth Minnesota Regiment in the Civil War, and for twelve years was a member of the State Legislature.

Dr. Shaleen attended Gustavus Adolphus Academy and College but left at the end of his junior year. He received his M.D. degree from the University of Minnesota Medical School in 1902, followed by an internship at the Swedish Hospital in Minneapolis. In 1910-11 he took postgraduate work in Vienna and Berlin and in 1918 served as Captain in the Medical Corps, being stationed at Atlanta, Georgia.

After World War I Dr. Shaleen resumed practice at Hallock, and it was due to his support that the Kittson War Veterans Memorial Hospital was established.

He was a member of the American College of Surgeons, a member of the Red River Valley Medical Society, the Minnesota State and American Medical Associations. He read and spoke Swedish, Norwegian, German, Italian, French, Spanish, Latin, and had considerable knowledge of Greek. He was an inveterate reader, and in his library were a number of volumes in French, Spanish and Italian. He donated 1,000 volumes to the public library at Hallock.

In 1930 Dr. Shaleen was a delegate from Minnesota to the Democratic National Convention in San Francisco. He was a Mason and a member of the Swedish Lutheran Church.

In December 16, 1937, Dr. Shaleen married Margaret Brighton Wallner who survives him.

* * *

FRANK DALE SMITH

Dr. F. D. Smith, since 1934 a practitioner at Rochester, Minnesota, died December 5, 1945, at the age of sixty-four.

Dr. Smith was born at Douglas, Minnesota, June 19, 1881. After attending Rochester High School, he graduated from the University of Minnesota Medical School in 1905.

He practiced twenty-four years at Kasson, Minnesota, and then moved to Rochester in 1934.

Dr. Smith married Pearl Olson of Oronoco June 12, 1912. His widow and two daughters, Dorothy E. Smith of Minneapolis and Mrs. Isabel J. Farnham of Rochester, and a granddaughter, Jane Page Farnham, survive him.

Dr. Smith was a member of the Presbyterian Church, a Mason, and a member of the Olmsted-Houston-Fillmore-Dodge County Medical Society, the Minnesota State and American Medical Associations.

Dr. John D. Van Valkenburg, Floodwood, and Dr. Alvin Sach-Rowitz, Moose Lake.

* * *

Dr. Ernest R. Anderson was re-elected president of Asbury Hospital in Minneapolis at the annual staff meeting on January 3. Dr. Henry E. Hoffert was elected vice president and Dr. Harlan A. Alexander, secretary-treasurer. Drs. Chauncey A. McKinlay, Herbert M. N. Wynne, Thomas A. Peppard and Leonard K. Buzelle were appointed on the advisory board.

* * *

After three and a half years in the Navy, Dr. J. Allen Wilson has resumed the practice of internal medicine in Saint Paul. Dr. Wilson served eighteen months aboard an attack transport and took part in the invasions of Sicily, Salerno and Southern France. During his final year of overseas duty, he was senior medical officer with rank of captain.

* * *

Dr. Carl H. Coombs, discharged from the Navy in January, is again in practice at Cass Lake. During Dr. Coombs' absence, the care of the white population of the district was taken over by Dr. Zachariah E. House and Dr. Robert Campbell, both of whom had been looking forward to retirement for some time, but who instead carried on valiantly under a constantly increasing load.

* * *

Dr. E. J. Baldes, of the bio-physics section of the Mayo Cinic has been on a three months' trip in England, France and Germany for research in aviation medicine. Dr. Baldes traveled as a civilian for the Air Technical Command at Wright Field, Dayton, Ohio. On his return to this country the report of his findings was made directly to the office of the Air Surgeon in Washington, D. C.

* * *

Dr. B. A. Weis, Saint Paul, has been discharged from service in the Navy and has opened an office at 814 Lowry Medical Arts Building for the practice of internal medicine. Dr. Weis became a Commander in the Navy, was stationed eleven months at the Great Lakes Naval Hospital, spent two years in the Pacific, on land and sea, and spent the last four months at the Naval Hospital at Medford, Oregon.

* * *

Dr. Arden L. Abraham was made chief-of-staff of Miller Memorial Hospital, Duluth, at the annual meeting on January 4. Other officers elected at the same time are: Dr. Anthon J. Spang, vice chief of staff; Dr. Keith Fawcett, secretary-treasurer; and Drs. Herbert O. Hoff and Philip Eckman, executive committee. Dr. Mario Fisher was made executive committee member ex-officio.

* * *

Dr. Carl Krause, formerly of the Community Hospital in Fairmont, has returned to his home there, but will hereafter be associated with Drs. Herbert B. and Robert B. Bailey at the Bailey Hospital.

Dr. Krause has been in the armed forces since August, 1942. His first assignment was Fort Snelling, where

Lt. Colonel Gerald H. Teasley, now a Fellow in urology at the Mayo Foundation, has been awarded the Legion of Merit for "performance of outstanding service." Formerly Director of the Military Personal Division, Office of Surgeon General, Washington, D. C., Dr. Teasley established a classification system for the Medical Department which was responsible for the best distribution of medical officers. He also prepared plans for demobilization to civilian occupations. According to the accompanying citation, Dr. Teasley's services "have been characterized by a high degree of proficiency surpassing that which might reasonably be expected of an officer in his position."

* * *

After an absence of five years in the Army Medical Corps, Dr. J. O. Meyer has returned to the Itasca Clinic at Grand Rapids.

A major in the General Headquarters Company, Seventh Division, Dr. Meyer participated in the initial landing on Attu and was on duty there and at Adack and Kiska until sent to Hawaii and assigned to the initial landings on Leyte. Dr. Meyer was at Okinawa from the assault until two weeks after V-J Day, when he was transferred to Korea.

While Dr. Meyer was away in service, Mrs. Meyer was employed at the University Hospital, where she was in charge of the Children's Clinic.

* * *

Dr. Charles Raadquist was made chief of staff of Hibbing General Hospital at the annual election of officers. Dr. Theodore A. Estrem was elected vice president and Dr. Arko, secretary. Department heads for the ensuing year are as follows: Dr. Clarence Jacobson, surgery; Dr. Carl N. Harris, medicine; Dr. L. William Morsman, opthalmology; Dr. Andrew Sinamark, otolaryngology; Dr. Edward W. Zeman, pediatrics; Dr. Theodore Estrem, obstetrics; Dr. A. Carlyle Tingdale, communicable diseases; Dr. Charles Raadquist, laboratory and x-ray. The resident physican is Dr. J. Cebula.

The annual banquet for the staff doctors is scheduled for the February meeting.

* * *

In an effort to remedy the sharp increase in communicable diseases reported by Dr. Frank J. Hill, city health commissioner, as a consequence of the housing situation in Minneapolis, Mayor Hubert H. Humphrey has organized a health advisory committee which includes the following from the medical profession: Dr. Charles E. Merkert, Hennepin County Medical Society; Dr. Frank J. Hill, city health commissioner; Dr. Donald W. Pollard, superintendent General Hospital; Dr. Edgar Huenekens, of the Board of Public Welfare; Dr. Gaylord Anderson, professor of public health, University of Minnesota.

In addition to assisting in the disposition of current problems, such as hospital expansion, construction of a new city hospital, modernization of General Hospital, policies of old-age assistance, care of convalescent and chronic cases, et cetera, the committee will function as a long-range planning board.

* * *

Absent from his offices in Canby for more than three years of service in the Navy, Dr. Leonard Monson returned to his practice shortly after the New Year. Later he will be joined by a partner, Dr. Raymond Chinn, with whom he worked in the South Pacific where they were attached to the same Marine Air Wing.

Dr. Chinn's home is in Washington, D. C., and he was in practice there when he was inducted into the Navy. Before moving to Canby, Dr. Chinn is taking some refresher courses.

Dr. Monson took part in the invasion of the Solomons with duty at Munda, New Georgia, Guadalcanal and Rendova. Returned to the States, he was assigned to recruiting service for a time, then was sent to Baltimore where he assisted in the commissioning of the *USS Typhoon*, a repair ship, and was aboard bound for Japan and nearing Hawaii when the war ended. Dr. Monson left the ship at Pearl Harbor and returned to this country. From then until discharged, he was at the Separation Center in Minneapolis.

* * *

Dr. Gordon L. Samuelson, who, prior to this entering military service had been practicing in Mankato for nine years, has re-opened his offices in the First National Bank Building.

Dr. Samuelson had been in service since September, 1940, when he enrolled in the Medical Field Service School at Carlisle, Pennsylvania. Following completion of his training, he was assigned to the adjutant general's office in Saint Paul and remained there until the National Guard was inducted into the regular army in January, 1941. He had twenty-six months of duty in the Aleutians and thirty-nine months overseas, with thirteen of them in the ETO in England, France, Belgium, Holland and Germany. He was a lieutenant colonel when discharged.

A graduate of the University of California, B.A., 1926, Dr. Samuelson received a B.S. from the University of Minnesota in 1929 and his medical degree in 1931. He has been a diplomate of the National Board of Medical Examiners since 1931.

During his terminal leave Dr. Samuelson took special work in urology at the University of Minnesota.

* * *

To meet the need of training more specialists in psychiatry and relocating medical men where psychiatrists are urgently needed, the National Committee for Mental Hygiene and the American Psychiatric Association have united to form a nationwide placement service. The service is designed especially to help physicians and psychiatrists make contact with training opportunities such as residencies, postgraduate courses and fellowships and to aid institutions in locating suitable candidates for appointment. Physicians interested in psychiatry are invited to send in full biographical statement including personal data, education, training, experience and special desires. Deans of medical schools, superintendents of hospitals and others employing or participating in the training of psychiatric personnel are invited to submit full information regarding available positions and sourses. Foundations, universities and other agencies are asked to report pertinent fellowships in psychiatry, psychosomatic medicine, and child guidance. Inquiries should be addressed to Captain Forrest M. Harrison (MC) USN, National Committee for Mental Hygiene, 1790 Broadway, New York City 19, N. Y.

* * *

The Hennepin County Medical Society has announced the return to practice of the following members:

Dr. Clarence Arlander, 2300 Central Avenue, a commander in the Navy, was in the South Pacific for twenty-two months. He served in Navy hospitals in New Caledonia and the Russell Islands and was attached to the staff of Vice Admiral Aubrey Fitch for nine months.

Dr. Donald B. Frane, 1214 Forty-second Avenue North, a captain in the Army, was overseas for twenty-three months. He was with a signal construction battalion on the Ledo-Stillwell Road for seventeen months.

Dr. Erling T. Hauge, obstetrician, Medical Arts Building, a colonel in the Army Air Force, was on duty in the South Pacific for thirty-three months.

Dr. John A. Haugen, obstetrician, Medical Arts Building, a lieutenant commander in the Navy, was with the Marine Division in the South Pacific for twenty-six months.

Dr. Donald McKinnon has resumed his surgery practice in his offices in the Medical Arts Building. A commander in the Navy, he served twenty months in the South Pacific and at Sebo Naval Base, Japan. For outstanding service at Iwo Jima and Saipan he was awarded the Bronze Medal.

Dr. Alexander J. Ross, 2723 East Thirty-eighth Street, a captain in the Army, was in New Guinea for eleven months.

Dr. Donald S. Simonson, general practice, 4151 Lyndale Avenue South, served as a major in the Army in England and Fort Logan, Colorado.

Dr. James E. Trow, 5748 Nicollet Avenue, an Army captain, entered service in October, 1944. Following duty in Alaska and on the Alcan Highway, he was assigned to Ashford General Hospital, White Sulphur Springs, West Virginia.

Dr. Wilford F. Widen, 2929 Bloomington Avenue, a commander in the Navy, had nineteen months of duty in the Admiralty and Philippine Islands.

Dr. Robert L. Wilder, 1801 Lyndale Avenue South, pediatrician, served as a major in the Army. He was on duty in England and Fort Logan, Colorado.

Dr. William Wolf, general practice, 1417 West Lake Street, has been engaged in Veterans Administration work.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

IEN WITHOUT GUNS. By Dewitt MacKenzie. 152 pages, 137 illustrations. $5.00 Philadelphia: Blakiston, 1945.

This book contains a résumé of some medical aspects f World War II, together with a series of illustrations roduced by the artists from their experiences in comat. The text, while not attempting to give a compreensive account, gives some highlights of the work of he Medical Corps from the lay outlook. It rightly lays up the heroic record of the Medical Corpsmen. The text, however, merely offers a backdrop for the exellent portrayal of medical scenes by the artists. Many f these pictures have been seen in various publications rinted by the Abbott Laboratories. As a collection of rtistic and historical value this book is well worth while.

S. W. Shimonek, M.D.

OCTORS AT WAR. Edited by Morris Fishbein, M.D., with the following contributors:

eorge B. Darling, M.D., Vice Chairman of the Division of Medical Science, National Research Council;
arold S. Diehl, M.D., Member of the Directing Board, Procurement and Assignment Servce, and Dean of the School of Medicine, University of Minnesota;
ajor General David N. W. Grant. The Air Surgeon;
harles M. Griffith, M.D., Medical Director, Veterans' Administration;
ajor General Paul R. Hawley, Chief Surgeon, ETO;
ajor General Norman T. Kirk, The Surgeon General, United States Army;
ajor General F. Lull, Deputy Surgeon General;
ice Admiral Ross T. McIntire, The Surgeon General, United States Navy;
aptain French R. Moore, Medcal Corps, United States Navy;
homas Parran, M.D., The Surgeon General, United States Public Health Service;
rigadier General Fred W. Rankin, Chief Consulting Surgeon, United States Army;
. Canby Robinson, M.D., LL.D., SC.D., National Director of the Red Cross Blood Donor Service;
olonel Howard A. Rusk, Chief of the Convalescent Training Divison, Army Air Forces;
rigadier General James Stevens Simmons, M.D., PH.D., D.P.H., Sc.D. (Hon.), Chief of the Preventive Medicine Service, United States Army. Illus. Price $5.00. New York: E. P. Dutton & Company, 1945.

This book is a brief survey of certain of the aspects of medical service in the war. It is a series of personal accounts by men concerned with some phases of the medical service. Each contribution has a self-explanatory title. Written by many, it necessarily is incomplete, and the style varies, but it is a readable and accurate account of the work of many agencies. Later, no doubt, more exhaustive treatises will be written.

Gordon C. MacRae, M.D.

THE OSSEOUS SYSTEM. A Handbook of Roentgen Diagnosis. By Vincent W. Archer, M.D. 320 pages, 148 plates. Chicago: The Year Book Publishers, Inc., 1945.

This work is one of six Handbooks of Roentgen Diagnosis, written by different authors and discussing different aspects of roentgenology. In general, the author presents, briefly but very clearly and efficiently, the important abnormalities of bone tissue caused by trauma or disease.

In this volume the material is presented under five

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address:

Registrar, 427 S. Honore St., Chicago 12, Ill.

principal headings: (1) Technique: Principles of Interpretation: Roentgen Anatomy; (2) Injuries to the Skeletal System Other than the Spine; (3) The Spine; (4) Bone Diseases and Abnormalities in Childhood; (5) Bone Diseases Occurring Principally in Adult Life. Under these main headings are given brief descriptions of various types of injuries and disease. The verbal discussions of individual disorders are adequately presented and accompanied by excellent illustrations. The author is careful in listing many points which may serve to avoid pitfalls or errors in diagnosis. Accordingly much emphasis is placed on proper technique of roentgenography in order to obtain sufficient knowledge of the part which is under study.

Although the book is intended for the occasional radiographer, it is considered to be useful also to those more experienced in the technical and diagnostic aspects of roentgenography of the osseous system.

R. J. Dittrich, M.D.

An average of about one out of every 100 children in the public schools of the United States has loss of hearing sufficiently great to be a handicap. Frequently such children have speech difficulties in accurately pronouncing words, with frequent omission of word sounds, especially finals. Often "t" is substituted for "k," "s" for "z" "tion" for "sh," and the long "e" may take the place of the short "e" or the short "i."

The voice of a child with hearing impairment may be a clue to his trouble. Sometimes the voice is unusually shrill and rasping; but not infrequently a deafened child speaks in weak, low tones.

Old Way...

CURING RICKETS in the CLEFT of an ASH TREE

FOR many centuries,—and apparently down to the present time, even in this country—ricketic children have been passed through a cleft ash tree to cure them of their rickets, and thenceforth a sympathetic relationship was supposed to exist between them and the tree.

Frazer* states that the ordinary mode of effecting the cure is to split a young ash sapling longitudinally for a few feet and pass the child, naked, either three times or three times three through the fissure at sunrise. In the West of England, it is said the passage must be "against the sun." As soon as the ceremony is performed, the tree is bound tightly up and the fissure plastered over with mud or clay. The belief is that just as the cleft in the tree will be healed, so the child's body will be healed, but that if the rift in the tree remains open, the deformity in the child will remain, too, and if the tree were to die, the death of the child would surely follow.

---

*Frazer, J. G.: The Golden Bough, vol. 1, New York, Macmillan & Co., 1923

It is ironical that the practice of attempting to cure rickets by holding the child in the cleft of an ash tree was associated with the rising of the sun, the light of which we now know is in itself one of Nature's specifics.

New Way...

Preventing and Curing Rickets *with* OLEUM PERCOMORPHUM

NOWADAYS, the physician has at his command, Mead's Oleum Percomorphum, a Council-Accepted vitamin D product which actually prevents and cures rickets, when given in proper dosage.

Like other specifics for other diseases, larger dosage may be required for extreme cases. It is safe to say that when used in the indicated dosage, Mead's Oleum Percomorphum is a specific in almost all cases of rickets, regardless of degree and duration. Mead's Oleum Percomorphum because of its high vitamins A and D content is also useful in deficiency conditions such as tetany, osteomalacia and xerophthalmia.

* * *

COUNCIL-ACCEPTED

Oleum Percomorphum With Other Fish-Liver Oils and Viosterol. Contains 60,000 vitamin A units and 8,500 vitamin D units per gram and is supplied in 10 c.c. and 50 c.c. bottles; and in bottles containing 50 and 250 capsules.

IS THE WET PACK TREATMENT

of superficial indolent ulcers and other skin lesions with TYROTHRICIN . . . a most important antibiotic agent.

TYROTHRICIN

used in wet packs or by irrigation, is effective against streptococcic, staphylococcic and pneumococcic infections of superficial tissues, deeper tissues made accessible by surgical procedures, and body cavities in which there is no direct communication with the blood stream.

The Massachusetts Indemnity Insurance Company offers you a comprehensive plan of income protection if you can qualify. It provides a regular income for you during disability from *either* sickness or injury.

SICKNESS INCOME

$........200.00........ per month during total disability, payable after the first........30........ days of such total disability and continuing for a maximum period of 8 1/3 years during each period of disability.

$........100.00........ per month during partial disability immediately following a period of total disability for which indemnity has been paid. Payable for six months in any period of disability.

ACCIDENT INCOME

$........200.00........ per month during total disability, payable from the........1st........day for........life time.........

$........100.00........ per month during partial disability immediately following a period of total disability for which indemnity has been paid. Payable for six months in any period of disability. (When accident total disability is payable from the first day, accident partial disability also is payable from the first day.)

ADDITIONAL HOSPITAL OR NURSE INDEMNITY

$........250.00........ per month if sickness or injury requires hospital confinement or the services of a professional nurse, payable from the first day for six months in any period of disability.

ALL, NOT JUST A FEW, of the following features are NECESSARY to give you the COMPLETE PROTECTION you NEED.

NON-CANCELLABLE Guaranteed renewable to age of 60.

INCONTESTABLE Incontestable after 2 years, similar to your life insurance policies.

WAIVER OF PREMIUM After 90 days of total disability, premium payments are waived until such disability terminates.

GRACE PERIOD In the payment of premiums, you are permitted a grace period of 31 days.

NO HOUSE CONFINEMENT It is never necessary to be confined within the house to receive the indemnities provided.

BODILY INJURY Indemnity is paid on the basis of the result of the injury, not the manner in which it occurred.

NON-PRORATING No reduction in indemnity because of change of occupation

NON-AGGREGATE The full policy limits payable for each new disability.

TOTAL DISABILITY Covers inability to engage in the insured's regular occupation, for 4 1/6 years, and thereafter for gainful occupation.

THIS MASSACHUSETTS INDEMNITY POLICY PROVIDES ALL OF THESE FEATURES

Silencer for midnight phones

When pediatricians prescribe 'Dexin' brand High Dextrin Carbohydrate for their infant patients, the physicians are no longer wakened so frequently by frantic late-night phone calls. Because of the high dextrin content, 'Dexin' feedings tend to (1) diminish intestinal fermentation and the resultant colic and diarrhea and (2) promote the formation of soft, flocculent, easily digested curds.

'Dexin' babies sleep more soundly, physicians' phones jangle less, and the doctor himself obtains more undisturbed sleep. Not unpalatably sweet, 'Dexin' is readily soluble in hot or cold milk or other bland fluids. 'Dexin' does make a difference.

'Dexin'

HIGH DEXTRIN CARBOHYDRATE

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available Carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

IN INFECTIONS COMPLICATING PREGNANCY, DELIVERY, and the PUERPERIUM

ACCUMULATING evidence* points to penicillin as a therapeutic agent of choice not only in puerperal and postabortive sepsis but also against infections complicating pregnancy (when the causative organisms are penicillin-sensitive). Since penicillin crosses the placenta into the fetal circulation, it may affect penicillin-susceptible infection in the fetus.

*Davis, C. H.: Gonorrheal Arthritis Complicating Pregnancy Treated with Penicillin, Am. J. Obst. & Gynec. 50:215 (Aug.) 1945.

Mitchell, R. McN., and Kaminester, S.: Penicillin; Case Report of a Patient Who Recovered from Puerperal Sepsis Hemolytic Streptococcic Septicemia, Am. J. Surg. 63:136 (Jan.) 1944.

White, R. A.: Puerperal Sepsis Treated with Penicillin, Southern M. J. 37:524 (Sept.) 1944.

PENICILLIN-C.S.C.

These features bespeak the physician's preference for Penicillin-C.S.C.: It is made under rigid laboratory controls which safeguard its potency, sterility, low toxicity, and freedom from pyrogens. The high degree of purification of Penicillin-C.S.C. is indicated by the pale color and small volume of the material in either the 100,000- or 200,000-unit vials. This makes untoward reactions comparatively rare, even when massive dosage and prolonged administration are required.

Most
DEPENDABLE
Method

The combined use of an occlusive diaphragm and vaginal jelly remains, in the published opinions of competent clinicians, the most dependable method of conception control.

Dickinson[1] has long held that the use of jellies alone cannot be relied upon for complete protection. It is noteworthy that in the series of patients studied by Eastman and Scott[2], an occlusive diaphragm was employed in conjunction with a spermicidal jelly for effective results. Warner[3], in a carefully controlled study of 500 patients, emphasized the value of a diaphragm.

In view of the preponderant clinical evidence in its favor, we suggest that physicians will afford their patients a high degree of protection by prescribing the diaphragm and jelly technique.

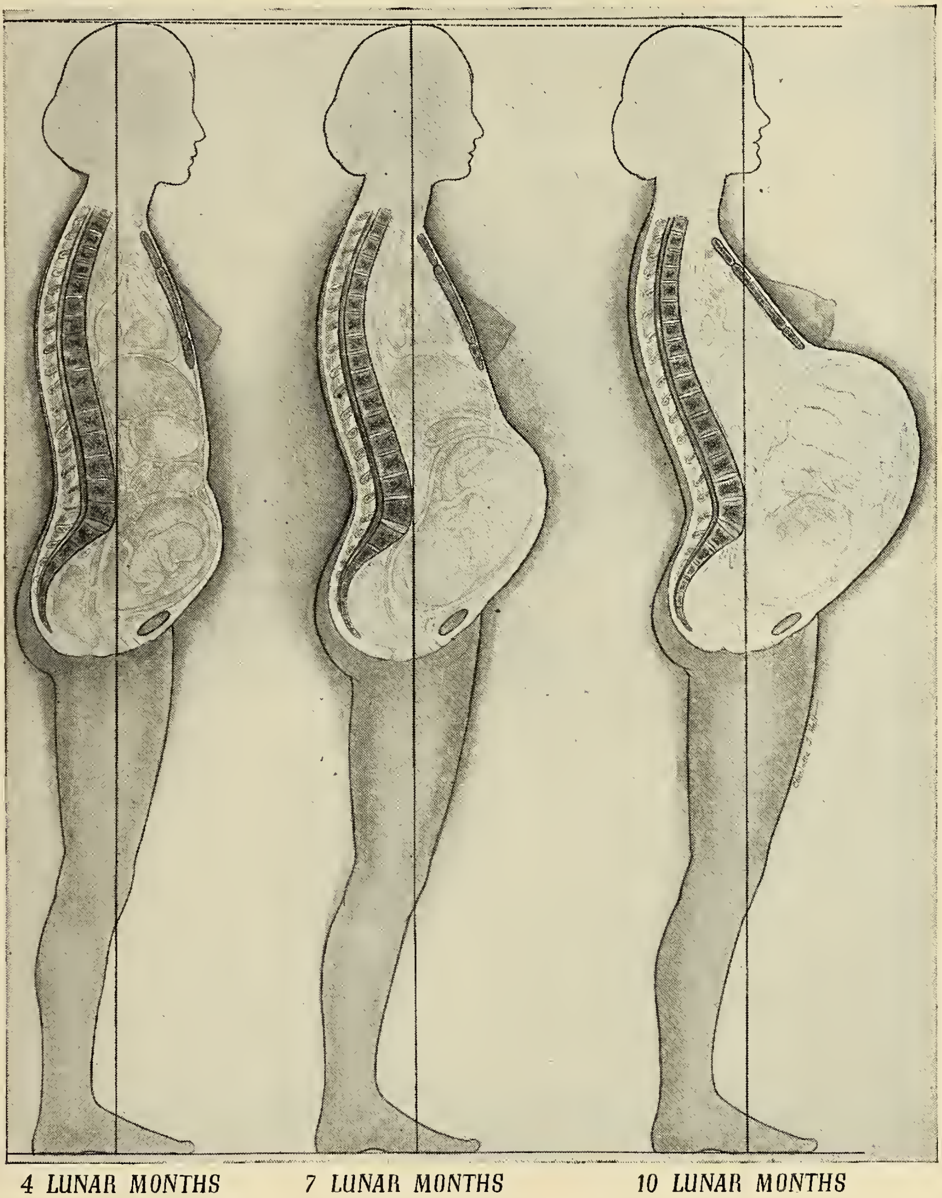
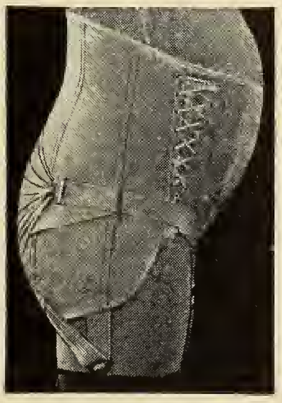
BODY MECHANICS OF PREGNANCY

• STUDIES FROM LIFE MODELS DURING PREGNANCY • Illustration by Charlotte S. Holt





The postural changes during pregnancy are due to the compensatory backward shift of the center of gravity caused by forward pull of the load of the pregnant uterus.

Note the retracted shoulders, carriage of head (pride of pregnancy), and the accentuation of the natural lumbar lordosis which relieves abnormal tension on back and leg muscles.

Camp Supports aid in reducing this forward traction and assist the mother in maintaining better balance.

IDENTICAL IN THERAPEUTIC ACTION WITH DIGITALIS LEAF . . .

Yet **ALL THESE ADVANTAGES**

DIGITALINE NATIVELLE
40 TABLETS
Alcohol 40%
VARICK PHARMACAL CO., Inc.
75 Varick Street
New York 13

COUNCIL ACCEPTED

THE cardiotonic action of Digitaline Nativelle is identical in all respects with that of digitalis leaf since it represents the chief, active glycoside of Digitalis purpurea—pure, crystalline digitoxin. Vagal slowing of heart rate, myocardial stimulation, and depression of conduction in the A-V node and bundle of His are readily achieved, followed by disappearance of heart failure symptoms.

In addition, however, Digitaline Nativelle presents these outstanding advantages:

CHEMICAL PURITY. The dosage of Digitaline Nativelle is measured in milligrams, thus providing uniformity of composition. One tablet of 0.1 mg. Digitaline Nativelle is therapeutically equivalent to 1 cat unit (1.5 gr.) of digitalis leaf. Hence the dosage, as far as the number of tablets is concerned, is the same.

FREEDOM FROM SIDE ACTIONS. Since it is absorbed in toto, probably from the stomach, Digitaline Nativelle produces virtually no nausea and vomiting due to local action. Adequate dosage may thus be given without fear of gastric upset, an important point in patients with congestive heart failure and their tendency to vomit.

RAPID, ORAL DIGITALIZATION IF DESIRED. In urgent situations, complete digitalization can be accomplished rapidly by oral administration, without side effects. The average dose for this purpose is 1.2 mg., given either at one time or in 2 doses of 0.6 mg. each at a 3 to 6-hr. interval. Digitalization is completed in 6 to 10 hours.

EASE OF DOSAGE CALCULATION. The average maintenance dose of Digitaline Nativelle is 0.1 mg. (1 tablet), the therapeutic equivalent of 1.5 gr. of digitalis leaf. Hence no new instructions to the patient are needed, since the two tablets are therapeutically equivalent. No greater caution is required with Digitaline Nativelle.

Physicians are invited to send for samples, literature and bibliography

THE ORIGINAL DIGITOXIN IN PURE, CRYSTALLINE FORM

WHEN *Living Itself* PROVES DIFFICULT

Stamina and strength, essential to a joyous, optimistic outlook, are vitally linked to the nutritional status, and will quickly wane if undernutrition is allowed to develop. Zestful living and boundless energy are hardly compatible with nutritional deficiencies.

For the below-par patient whose inadequate nutritional intake is the responsible factor, Ovaltine as a dietary supplement can make a real contribution toward assuring nutritional balance. A good source of high-quality protein, readily utilized carbohydrate, well-emulsified fat, and essential vitamins and minerals, Ovaltine can prove a significant factor in restoring the desired state of optimal nutrition. Three glassfuls daily, made with milk as directed, provide appreciable amounts of essential nutrients as indicated by the table. The low curd tension of Ovaltine assures rapid gastric emptying, hence the appetite for regular meals is not impaired. Ovaltine is enjoyed as a beverage and between meals.

PROTEIN

*"As a Prophylactic and Therapeutic Agent"**

"There are many opportunities for practical dietary application of the advances in our understanding of protein economy. The provision of liberal protein diets in instances where the value of protein has been demonstrated offers both prophylactic and therapeutic advantages to the patient."

PREGNANCY AND LACTATION

"Protein is one of the essentials for which there is greater need.... The growth needs of the fetus must be met and if adequate dietary protein is not supplied, the mother's protein stores will be drained. . . . The demands for protein during lactation are even greater.... One further reason for providing a liberal supply of protein... lies in the favorable effect which protein has upon calcium absorption."

DISEASES OF THE KIDNEY

". . . actual improvement in the well-being of nephritic patients may be observed following the use of high-protein diets both in adults and children. In some instances functional capacity of the kidneys has been reported to improve on such a regime.... For the treatment of nephrosis the same dictum holds true, only to a greater extent. . . ."

DISEASES OF THE LIVER

"For many years carbohydrate alone has been considered the one substance capable of providing protection for the liver cells. ... Protein has now been shown to be considerably more effective in this respect. ... The effect of protein on the liver is not only reparative, but also definitely protective against the agents known to be toxic to the liver. . . ."

PEPTIC ULCER

". . . a rather high incidence of moderate hypoproteinemia in peptic ulcer cases has been reported. Any ulcer, be it peptic, infectious, or the result of pressure and circulatory changes, represents a loss of tissue and requires protein for rebuilding. . . ."

OTHER CONDITIONS

"In old age, for instance, all too often the food intake deteriorates to soft foods of limited variety.... Yet in such instances the same protein requirements for maintenance of the numerous body functions are still in effect. . . . Protein may also be lost because of its excessive breakdown under the influence of fever or heightened body metabolism, and negative nitrogen balances may develop, as for instance in hyperthyroidism. . . .

"With the demonstration of this increased importance of protein dietetic therapy, it can only be recommended that there be an increased use of high-protein diets."

Among the protein foods of man meat ranks high not only because of the percentage of protein contained, but primarily because the protein of meat is of high biologic quality, applicable for every protein need.

WHY DO TOM, DICK AND HARRY NEED VITAMIN D?

Growing children require vitamin D mainly to prevent rickets. They also need vitamin D, though to a lesser degree, to insure optimal development of muscles and other soft tissues containing considerable amounts of phosphorus . . . Milk is the logical menstruum for administering vitamin D to growing children, as well as to infants, pregnant women and lactating mothers. This suggests the use of Drisdol in Propylene Glycol, which diffuses uniformly in milk, fruit juices and other fluids.

A NUTRITIONALLY ADEQUATE INFANT FOOD

FORMULAC is the trade-name for a new product—a reduced milk in liquid form—supplemented with sufficient vitamins and minerals to render it an adequate food for infants.

FORMULAC was developed by E. V. McCollum to fill a long-felt pediatric need for a milk containing sufficient vitamins and minerals to meet the nutritional requirements of a growing infant *without supplementary administration.* The McCollum method of incorporating vitamins into the milk itself eliminates the risk of maternal error or oversight.

FORMULAC, newly introduced on the market, is promoted ethically.

FORMULAC, supplemented by carbohydrates at your discretion, presents a flexible basis for formula preparation, readily adjustable to each individual child's needs.

FORMULAC has been tested clinically, and proved satisfactory in promoting infant growth and development. Priced within range of even low income groups, this inexpensive infant food is on sale at most drug and grocery stores.

GLOBIN INSULIN
Action carries over beyond 24 hrs.
Delayed acting INSULIN
Consider all 3 insulins for better diabetes control...

THE physician now has three types of insulin available to treat diabetes. One is quick-acting but short-lived. Another is slow-acting but long-lived. The new third one—'Wellcome' Globin Insulin with Zinc—is intermediate.

Action with Globin Insulin begins moderately quickly and persists for sixteen or more hours, sufficient to cover the period of maximum carbohydrate intake. By night, activity is sufficiently diminished so that the likelihood of nocturnal reactions is minimized. A single injection daily of 'Wellcome' Globin Insulin with Zinc will control the hyperglycemia of many diabetics. When a diabetic requires insulin therapy, the physician is wise to consider all *three* insulin types.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties.

Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in the Wellcome Research Laboratories, Tuckahoe, New York. U. S. Patent No. 2,161,198. Available in vials of 10 cc., 80 units in 1 cc.

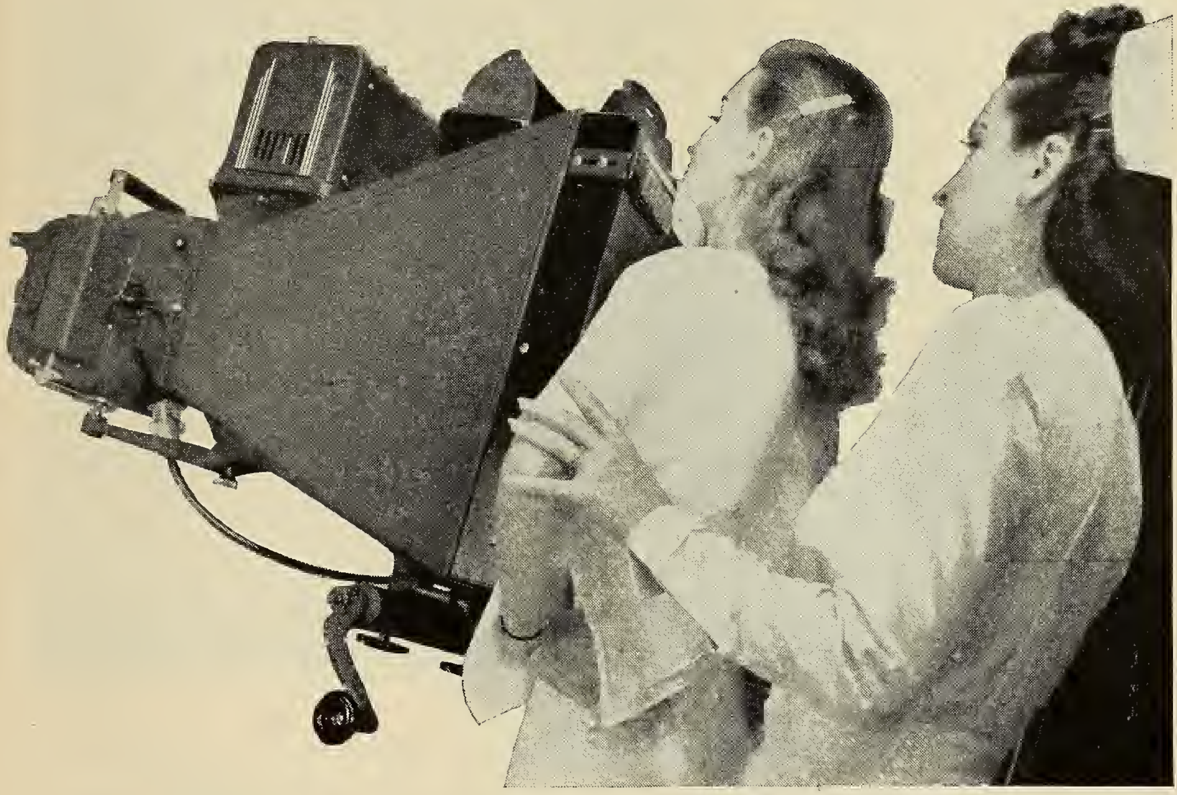
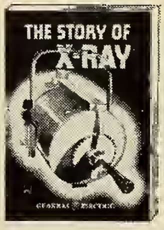
Is Your Community Awaiting an X-Ray Chest Survey?



Through well-directed educational campaigns sponsored by tuberculosis organizations throughout the nation, men, women, and children have been learning about technological developments which today make it economically feasible to conduct x-ray chest exminations of large groups of people for the purpose of detecting unsuspected tubercular infections in apparently healthy individuals.

Public interest having been so thoroughly aroused, many communities have adopted individually planned x-ray chest survey programs as a most effective measure for tuberculosis control—for screening out and isolating individuals who, "ignorant of the fact that they have the disease, unknowingly jeopardize their own lives and the lives of those with whom they come in contact."

Come the time when such a survey is suggested for your community, and your professional advice probably sought by the local tuberculosis society, we shall be glad to help you prepare a summary which would evaluate the various methods and facilities used for different types of chest surveys. These evaluations, may we assure you, will be unprejudiced, as G-E photo-roentgen apparatus is not limited to but one model, nor restricted to the use of one size of film. Address General Electric X-Ray Corporation, 175 W. Jackson Blvd., Chicago 4, Illinois.



For Your Reception Room— this booklet will prove of absorbing interest to waiting patients. It commemorates the 50th Anniversary of the discovery of x-ray, and recounts the notable contributions of x-ray science, not only to medicine but also to many important phases of industry. Send for your complimentary copy. Ask for Pub. C13.

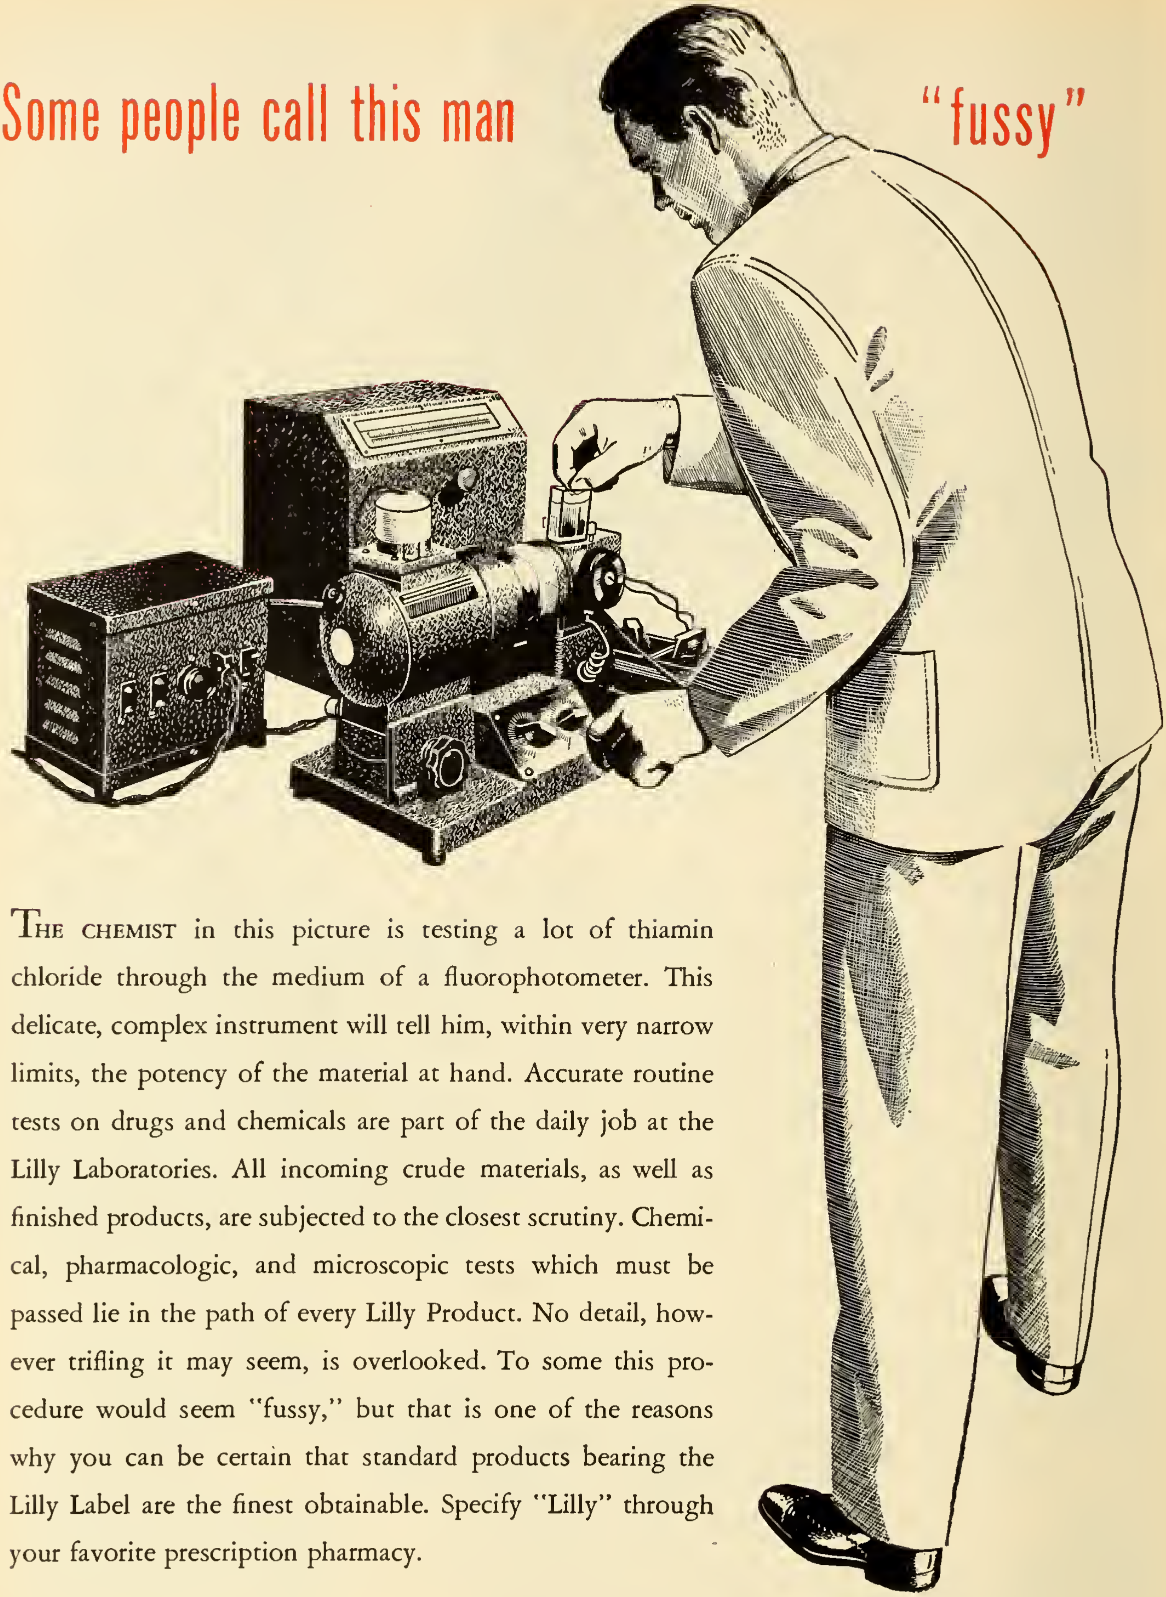
Some people call this man "fussy"



THE CHEMIST in this picture is testing a lot of thiamin chloride through the medium of a fluorophotometer. This delicate, complex instrument will tell him, within very narrow limits, the potency of the material at hand. Accurate routine tests on drugs and chemicals are part of the daily job at the Lilly Laboratories. All incoming crude materials, as well as finished products, are subjected to the closest scrutiny. Chemical, pharmacologic, and microscopic tests which must be passed lie in the path of every Lilly Product. No detail, however trifling it may seem, is overlooked. To some this procedure would seem "fussy," but that is one of the reasons why you can be certain that standard products bearing the Lilly Label are the finest obtainable. Specify "Lilly" through your favorite prescription pharmacy.

FACTORS IN RURAL HEALTH IN MINNESOTA

EDWIN J. SIMONS, M.D.
Swanville, Minnesota

It is indeed a pleasure and a privilege to be with you today. This, I believe, is particularly true since one of the objectives of the Farm Bureau is also one of the goals of the Minnesota State Medical Association. This common objective is to see that all of the people of the state, farmers as well as others, are provided adequate high-quality medical care at a cost which they can afford. My remarks today will attempt to portray present conditions of rural health in Minnesota and the efforts being made by the organized medical profession to see that adequate good medical care is available in the near future at low cost.

Before the war, and it is hoped that with military physicians returning to civilian practice, these conditions will soon be repeated; there were 3,600 practicing physicians in Minnesota. Of this number 1,800, approximately, practiced in the urban centers—Minneapolis, St. Paul, Duluth and Rochester. In these centers of population, there were about 1,000,000 of the state's 2,700,000 population. Thus, then, 1,800 physicians provided medical care for 1,700,000 people living in rural districts.

During the war, induction of civilian physicians into the military forces created some maldistribution of civilian physicians. In fact, during the war, there were several instances in which persons living in rural districts had to travel excessive distances for medical care. But before the war, two surveys were conducted, one in 1934 and the second through the press in 1941, to determine whether physicians were readily accessible to all people in Minnesota. Both of these surveys showed that beyond question doctors were available to practically all of the people of the state. It is anticipated that some of the maldistribution of physicians resulting from the war will soon be corrected by the return of military physicians to civilian practice.

The next question that presents itself is, "Under these circumstances, what has been the state of health of the people of Minnesota?" The death rate from all causes has been slightly lower in Minnesota than in the United States as a whole. Life expectancy has increased from forty-nine years at the turn of the century to sixty-one and sixty-five years in 1945 for males and females, respectively. The maternal mortality, newborn and infant mortality rates in Minnesota have been the best of any but one or two states in the Union. The mortality rate from infectious diseases in Minnesota ranks Minnesota among the leading states in public health and preventive medicine. The mortality rate in tuberculosis in Minnesota has decreased to less than one-fourth of what it was in 1910. In fact, in a recent article by Dublin in the *American Magazine*, Minnesota ranked second among all the states of the United States in matters of health.

It appears only reasonable to assume that adequate high-standard medical care is available to all people in Minnesota or the conditions just described could not be true. There are three other factors which are largely responsible for the excellent health of the people of Minnesota. They

---

Address of the President of the Minnesota State Medical Association before the 27th Annual Meeting of the Minnesota Farm Bureau Federation at the Hotel Lowry, St. Paul, Minnesota, January 14, 1946.

are: (1) the Minnesota Medical School and University Hospital, (2) the Minnesota Department of Health, and (3) the Mayo Clinic at Rochester. Through these three agencies, the very latest measures in diagnosis, treatment and preventive medicine are made available to the general practitioners and the people of the state. All of these institutions have national and even international reputations which have placed Minnesota in the foreground in all fields of medicine.

So, we arrive at the question, "How is the cost of adequate high-standard medical care to be reduced?" So far as hospital care is concerned, the question has been answered in the Blue Cross Hospitalization Plan. Already, approximately 25 per cent of the state's population participates in this plan. Also, it is anticipated that further increases in hospital beds will be available in the not-too-distant future as a result of the recent passage by Congress of the Hill-Burton Hospital Bill. Governor Thye has already appointed a committee of twenty-four members to study the need of additional hospital facilities throughout the entire state of Minnesota. The federal bill provides as much as 100 million dollars a year for the construction of hospitals. What portion of this may be allocated to Minnesota is dependent on the findings of the committee as well as other factors involved.

Prepaid medical care in Minnesota perhaps should be mentioned under three headings, such as: (1) Plans already in operation, (2) state plans, and (3) national plans affecting Minnesota.

Under the first subdivision falls the Farm Security Administration medical care program. Such plans are now in their fifth year. Originally, farm families of the marginally indigent group in Otter Tail, Mille Lacs and Morrison Counties were eligible to participate. At present the plan is operative only in Morrison County. Participation costs $30 per year per family. Families average 5.2 persons. All medical care except non-emergency surgery is provided in the plan. Free choice of physicians is assured the families.

For the first two years the annual cost per family was $23 instead of $30. During this period the number of families eligible for participation dropped about 50 per cent. Also, during this period it was difficult to convince families that they should join. During the past two and one-half years, even with the annual family cost raised to $30, families voluntarily request membership. In fact, the plan has been so successful from the farmer's point of view that many outside families have had to be refused the privilege of participating.

In the second group, state plans first crystallized at the last session of the Minnesota State Legislature. Then, at the instigation of the Minnesota State Medical Association, enabling legislation was passed for the inauguration of a state-wide prepaid medical care plan. Already twenty-four physicians throughout the state have been chosen to serve as organizing directors of the plan. These twenty-four physicians have been organized in four subcommittees to arrange articles of incorporation, organization and administration, contracts and fees and funds necessary for incorporation. Several meetings of these subcommittees have been held. Articles of incorporation have been drafted but not approved. Discussions are being held concerning the coverage of such contracts. That is to say, it is not known at present whether all medical, surgical and confinement services will be included or whether only surgical and confinement cases will be covered. Also, it has not been determined whether administration will be linked with the Blue Cross Hospitalization service.

It is expected that contracts probably can be purchased by anyone. Free choice of physician is assured contract holders. It is hoped and expected that the contracts will be within the financial reach of all who desire to purchase them. It is not known when the plan will become operative, but these facts have been given you to keep you abreast of the plans to date. Suffice it to say that energetic efforts are being made by the Minnesota State Medical Association to see that prepaid medical care of high quality will soon be available to all people in Minnesota.

National plans, the third category, is one factor which is causing some delay with present state plans. The American Medical Association is considering a national prepaid medical care plan which will cover all states. It is anticipated that some time during the month of February more definitive action will be taken on this federal plan. Until it is known whether or not the national plan is soon to be organized it is not entirely clear whether the final steps in organizing the Minnesota plan should be taken. But it is clear that soon, through either one or the other of these developments, prepaid medical care con-

(Continued on Page 258)

TROPICAL DISEASE HAZARDS IN THE NORTHWEST

R. W. BACKUS, M.D.

Nopeming Sanatorium, Nopeming, Minnesota

TO the average American physician the subject of tropical medicine has a very alien sound. But one of the many things we have learned in recent years is that what is alien is not necessarily unrelated to us. Not long ago Corregidor, Anzio, and Okinawa were strange and curious sounds, but the war brought them to our front door. And as our servicemen and women return they will bring with them medical problems with which we must become acquainted, tropical diseases of which we may hardly have heard, yet which potentially threaten our national health.

In considering tropical medicine, it must be recognized that the term tropical is loosely applied, and not strictly geographic in meaning. Certain tropical diseases, it is true, occur only in the Tropic Zone. But others are more widespread, occurring throughout the world, though more common in the tropics and Orient where climate, dense population, social habits, and poor hygiene provide a more favorable environment for them. Some are even now endemic in the United States, while others have appeared here as epidemics in the past.

The possibility of spread of tropical diseases by returning service personnel depends on a number of factors, of which two are most significant. The first is time. Meleney[22] points out that acute diseases with short periods of communicability such as yellow fever, typhus, plague, and cholera, develop and run their course quickly; hence, if encountered at all, will be dealt with while the veteran is still en route home, or before discharge. They therefore have little chance of establishment in the United States and civilian doctors run even less chance of meeting them. In contrast are those diseases which are chronic, with a long period of incubation or communicability; hence, a chance to bridge the period of demobilization. Such are malaria, the dysenteries, and the helminth infestations. These we will undoubtedly see to a greater or lesser degree.

A second factor determining hazard of introduction or spread of a particular disease is means of transmission. Some are bacterial in origin and transmitted directly. Some are carried by insects or require presence of other animals as intermediate hosts. Such diseases can be brought back by the returning veteran, but can be transmitted to others only if the proper insect vector and intermediate host occur here.

Practically, therefore, the physician may expect two types of tropical disease problems in his practice. The first may be illustrated by bacillary dysentery, a bacterial infection, or amebiasis, a protozoal disease; either of these may be communicated by direct fecal contamination, or indirectly by the housefly. Such diseases may be seen either in the returning veteran or in the civilian whom he contacts. The second type will be seen only in the veteran. It is well illustrated by African sleeping sickness or trypanosomiasis, which requires the tsetse fly for transmission. This insect is not native to America, and its introduction is not likely. It is quite probable that an occasional serviceman from Africa may carry the disease home unrecognized, and thus come to the physician for diagnosis. But passage of the disease to others is and will remain extremely unlikely, if not impossible. We need not look for it in those who have not been in Africa. This brings out a significant point in dealing with all exotic diseases: ask where the patient has recently been.

Malaria

Turning now from general principles to specific diseases, authorities agree that of all hazards to be anticipated, the chief is malaria. Branch[2] and Getting[14] emphasize that it is the most common, widespread, and lethal disease of man. Throughout the world it is estimated to kill over three million annually. "After disembarkation and demobilization, all previously malaria-free individuals will cease prophylactic treatment. Any change in living may bring out the disease. Already we are having deaths from such disease treated too little and too late." Surgeon General Parran[25] says, "Outside of mental diseases, there is no other disease of comparable importance against which we have made less progress during my generation." Malaria in varying degree is present in most of the countries to which our forces have gone—Africa, the Mediterranean basin, Asia, South Pacific, East Indies, and South America.

As to etiology, the parasitic plasmodia are carried by various species of Anopheles, several of which occur in the United States. The only one of significance in this area, however is A. quadrimaculatus. This mosquito is fairly common throughout southern Minnesota, the eastern Dakotas, and on east and south to the Atlantic border. It is well known that malaria was endemic in much of this region in years past, but modern screening, better mosquito control, improved care of the malaria case, and perhaps climatic factors inimical to the parasite have made the disease relatively uncommon. Returning service personnel will undoubtedly serve as a pool of malaria infection which may again establish the disease for a period of years unless a well-planned defense is provided by State or Federal public health authorities. The possibility of introduction of some other mosquito vector hitherto unknown in this region is also to be noted, particularly in this era of air transport. Anopheles gambiae was thus introduced into Brazil from Africa some years ago leading to a disastrous epidemic. Public health authorities moved in and finally eliminated the mosquito by a classic anti-mosquito campaign, but only after a program lasting two to three years and costing two and one-half million dollars.

In considering malaria clinically, one must not forget its pathology. The parasites involve primarily the reticulo-endothelial system, leading to splenomegaly and anemia. In addition, there may be liver enlargement and parasitic invasion of capillaries of the brain, meninges, lungs, and intestine, causing cerebral and other complications. Renal damage may be revealed as blackwater fever, due to acid hematin deposits in urinary tubules. The classic picture of remittent fever occurring at forty-eight- or seventy-two-hour intervals is well known. It must be understood, however, that such nice regularity is not to be expected in every case, or even the average case, particularly in this region. Any unexplained fever, no matter whether regular or irregular, marked anemia, splenomegaly, recurrent diarrhea, or sudden, severe cerebral manifestations require immediate and intensive blood smear examination for parasites, if the patient has formerly been in an endemic malaria region. Diagnosis must be based on positive blood findings; smears should be prepared by both thin and thick film techniques, and should be repeated on consecutive days if initially negative.

The laboratory differentiation of the several malaria parasites is not merely of academic interest. It is of definite importance in treatment and prognosis. It is generally agreed that quartan and ovale forms are not to be expected commonly in the United States. Differentiation will, therefore, lie chiefly between the vivax and falciparum or aestivoautumnal strains. All authorities agree that falciparum malaria is the more vicious type, with parasites sometimes invading up to 5 per cent of the red corpuscles, leading to severe cerebral and meningitic manifestations and the dreaded blackwater fever. On the other hand, Butler and Sapero[5] point out that as seen in the South Pacific, falciparum malaria has relatively low inclination to latency, with a recurrence rate of only 5 per cent; hence it is less likely to be carried into the United States. Also as Meleney[23] notes, it is more amenable to suppression by prophylactic use of atabrine.

The commoner tertian or vivax malaria as found in the South Pacific is said, on the other hand, to be very chronic, resistant to atabrine, tending to recurrence over a long period of time. It is two to three times as apt to recur as our domestic strain of tertian malaria, and may be expected to continue in a patient for an average of two or more years.

The treatment of malaria has had interesting developments as a result of the war. For example, Talbot[31] reports on two groups of men in the South Pacific endemic area. An army group was given routine suppressive doses of atabrine. A navy group in the same area was treated only as clinical malaria appeared. Later a survey of the two groups showed that 48 per cent of the army men had latent malaria as shown by positive blood smears, as compared with 66 per cent of positives in the untreated navy group. Further, clinical malaria developing in the army group during suppressive treatment tended to be more severe than in the untreated navy men. This and other similar experiences have led to the belief that where proper laboratory facilities exist, it is better to omit suppressive therapy even in heavily endemic areas, and treat only active clinical cases.

Routine treatment is thoroughly covered in the Surgeon General's Circular Letter No. 153.[29] It is here emphasized that the plasma level of antimalarial drugs is fundamental in determining their efficiency. Of the two commonly used drugs, quinine localizes less in the tissues and so acts sooner, while atabrine first saturates the tissues and thus acts longer but more slowly. For suppressive therapy, advisable only when troops must be inadequately protected in heavily endemic regions, the recommended dosage is: atabrine 0.1 gm. at the evening meal 6 days a week, or quinine 0.6 gm. daily at the evening meal. For proper suppression the drug must be taken regularly.

For clinical treatment of the active uncomplicated case, recommended therapy is: atabrine 0.2 gm. with 1 gm. sodium bicarbonate in 200 or 300 c.c. of water or fruit juice every six hours for five doses, then 0.1 gm. t. i. d. p. c. for six days; or quinine may be given, 1 gm. t. i. d. p. c. for two days, then 0.6 gm. t. i. d. p. c. for five days. In falciparum cases, to control the gametocyte or sexual stage, plasmochin may be necessary, though it is a toxic drug and must be used with caution; give it after a course of atabrine, or along with quinine, 0.01 gm. three times daily for four days, with 1 gm. sodium bicarbonate per dose. For severe cases, or those with complications of vomiting or coma, atabrine is preferred, in doses of 0.2 gm. in 5 c.c. of sterile distilled water intramuscularly in each buttock, repeated one or two times at intervals of six to eight hours if necessary. Turn to oral medication as soon as possible such that total dosage is 1 gm. in forty-eight hours, then 0.1 gm. t. i. d. p. c. for five days; or quinine may be given, 0.6 gm. in 300 to 400 c.c. sterile isotonic salt solution intravenously, repeating if necessary, and following with atabrine or quinine by mouth as soon as possible. Treat relapses the same as first attacks. If relapse is suspected, but blood smears negative, parasites may usually be demonstrated after giving epinephrin, 0.5 c.c. of 1/1000 solution subcutaneously. In all malaria treatment, possibility of quinine or atabrine sensitivity must be kept in mind, in which case the other drug must be relied on alone. Totaquine, the purified total alkaloids of cinchona, may be used as a substitute for quinine, in equal dose.

Helminth Infestations

Turning now to worm diseases, the commonest throughout battle areas has presumably been ascariasis, due to the roundworm often found in the United States. The life cycle of this worm involves passage of eggs in the stool, contamination of water or food, particularly vegetables or fruits, and re-entrance to the human intestinal tract. Here the egg hatches, the larva penetrates intestinal capillaries, is carried to the lung, penetrates the alveolar wall, is coughed up to the larynx, reswallowed, and develops into the adult worm, ready to produce more eggs. Preferred treatment is hexylresorcinol (coated pills) 1 gm. on an empty stomach, followed in an hour by a saline cathartic. This is also effective against pinworms and whipworms.

Hookworms are fairly common in the more cultivated wet areas in the Pacific, but the disease picture is sufficiently well known in this country not to require special discussion here.

Filariasis, a roundworm infestation of different type, has appeared rather frequently among troops in certain South Pacific regions. By its very nature, causing tissue swelling, edema of the lower extremities and genitalia, and sometimes elephantiasis, it has been much feared by servicemen and many physicians. The disease has existed for many decades as an endemic focus in Charleston, South Carolina, to which it was brought by the slave trade. Due to natural conditions unfavorable to the parasite, the disease has almost disappeared there. As seen in the Pacific, the complaint is prevalent in rather sharply limited areas where dense population and presence of a suitable mosquito carrier have made a fertile field for the infection when once introduced. The cycle begins with sucking up of microfilariae or young parasites by a mosquito, Culex fatigans or other suitable vector; the parasites invade the mosquito thorax muscles, migrate to the proboscis as larvae, and are re-deposited in man, find their way to lymphatics, and there mature, producing their microfilarial young. The worm, called Wuchereria bancrofti, is hair-like in diameter, 2 to 3 inches long, and by preference locates in lymphatics of the groin and genitalia. Clinical symptoms appear only when parasites are introduced in considerable numbers by frequent mosquito attacks. Troops soon moved from an endemic area apparently suffer little damage from an early infection. Even though considerable swelling has appeared, it is noted that in nearly all cases the lymphedema quickly and permanently disappears on return to a temperate climate. Diagnosis of early cases may usually be made by finding enlarged epitrochlear glands and a rubbery swelling of the spermatic cord. An intradermal diagnostic test using an antigen prepared from Dirofilaria immitis[32] has been reported valuable in detecting early suspects. Holmes[17] recommends excision of enlarged nodes when troublesome. No other specific therapy would appear necessary in areas where proper mosquito carriers do not occur, but where more aggressive therapy appears indicated, lithium antimony thiomalate, as recommended by Brown,[3] would appear promising. Stibamine glucoside[10] ("neostam"), useful in kalaazar, has also been suggested.

Onchocerciasis and loa loa, causing fugitive subcutaneous swellings, may possibly be seen in returning troops, and will be of clinical significance, we are told, chiefly when involving the eye, causing conjunctival swellings and occasionally blindness. Dracontiasis or Guinea worm may perhaps occur as subcutaneous swellings and blisters of the legs and feet. Local treatment may be necessary. None of these maladies can be expected to spread in this country.

Tapeworm and echinococcus infections may be dismissed as unlikely hazards in the United States, resulting only from the use of grossly contaminated water or food, a point strictly watched by the army sanitation authorities.

Blood Flukes

Diseases resulting from infection by various flukes are, in contrast, expected to appear in varying degree. Several types, Fasciola hepatica, Chlonorchis sinensis and others, are unlikely, requiring as they do the eating of uncooked fish, etc. Real hazard exists in the case of the schistosome group, however; the eggs of these parasites are passed in the stools or urine, develop in fresh water into ciliated larvae, invade certain species of snail, re-emerge into the water, and penetrate the skin of man when he wades or bathes there. They proceed to the capillaries of the intestine, urinary bladder, or lung, and there mature, and from those organs the eggs enter the stool or urine. Due to the nature of war, with land troops frequently subject to immersion in contaminated pools and streams, it appears unavoidable that infections must occur in endemic areas. Schistosoma hematobium heavily infests North Africa and to a less extent other parts of Africa and the Near East. Clinically it involves chiefly the venous plexus about the urinary bladder, causing bladder wall abscesses, urgency, pain, and hematuria. S. mansoni occurs widely in Africa and northern South America; S. japonicum is found in Japan, Central China and the Philippines. Both these diseases center mainly in the intestine, with dysenteric symptoms and bowel ulceration, but secondarily may show marked splenomegaly and hepatomegaly. Diagnosis of all forms is through isolation of the parasitic eggs. Treatment is specific, using trivalent organic or inorganic antimony, of which the best is neoantimosan (fouadin) intramuscularly or intravenously. Emetine is also effective, but must be used with caution.

So far as is known at present, schistosomiasis cannot be spread in the United States due to absence of suitable intermediate hosts, certain freshwater snails. However, it is possible that facultative hosts may develop among our own snail species; investigations are now being carried out along this line. Certainly the disease should be watched for among returning veterans, for if present, it is of serious import.

The Dysenteries

The chief advance in the subject of the dysenteries recently has been in the classification and therapy of bacillary dysentery. Callender[6] and others, advocate that this term be broadened to include not only the Shigella dysenteries of Shiga, Flexner, Sonne, et cetera, but also the severe diarrheas of the Salmonella group. It has also been suggested that the Shigella dysenteries be called Shigellosis, paralleling the term brucellosis. All of the intestinal bacillary infections are common under war conditions, particularly in the Orient, and have occurred numerous times among service personnel. Differential diagnosis clinically is most accurately done through careful stool examination, including culture on special media. However, careful epidemiologic analysis will also point to a diagnosis in many instances. Thus an epidemic of food poisoning appears within a very few hours after the ingestion of the causative food, is violent, but should quickly clear under proper treatment. Salmonella infections show up as epidemics, but with an incubation of hours or days, with fairly acute fever and general constitutional symptoms, subside more gradually. Shigellosis varies much more in incubation interval, from days to weeks, shows less in the way of fever and general symptoms, but causes more serious bowel inflammation, with ulceration, bloody stools and tenesmus, continuing over a longer period of time. Amebiasis occurs as a much more sporadic disease, varying from very mild to severe, and from acute to extremely chronic. For cases particularly difficult to diagnose, the taking of swabs by the technique of Watt and Hardy[16] may help.

Therapy of the bacillary dysenteries[4,12] should begin with 2 to 4 drams of saturated sodium sulphate solution; after two hours give sulfaguanidine or sulfasuxidine 5 gms. q.i.d., or sulfadiazine or sulfathiazole, 1 gm. q.i.d. for two days, then t.i.d. until the stools are normal for two to three days. It is well to check by daily stool culture until two or more daily cultures are negative. Some authors prefer sulfaguanidine, while others prefer the soluble drugs, particularly sulfadiazine.

Though affecting many of our troops while abroad, bacillary infections run too short a course and are too well controlled by adequate epidemiologic measures to threaten serious epidemic spread in this country. All of the infections mentioned are already found here frequently as a matter of fact, and such sporadic outbreaks may be expected to continue.

Amebiasis has been the subject of numerous surveys in the United States, with reports of incidence up to 15 per cent or more. The great majority of cases are silent or minimal symptomatically, hence, seldom secure treatment. Acute, fulminating cases may occur, however, as well as the less common hepatitis and liver abscesses. Diagnosis in the acute case through identification of motile amebae in a warm, fresh stool is a relatively simple procedure. For demonstration of cysts in the chronic case or carrier, rectal swabs may be necessary, with staining by special methods of Faust and D'Antoni.[13] Treatment of the acute case of dysentery or liver amebiasis should begin with emetine hydrochloride, gr. i hypodermically for six days or less. Emetine is a potent myocardial poison and administration must be guarded. In chronic cases, and following emetine in acute cases, any one of several preparations may be used. Carbarsone, an arsenical, is given twice daily for ten days, and in more critically ill patients is given in enemas. Chiniofon (yatren) is an iodine derivative much used formerly, but less in favor as other preparations have been found. Diodoquin, 1.5 to 2 gm. b.i.d. for ten days, or vioform, 0.25 gm. t.i.d. for ten days are also recommended, particularly in subsequent courses of treatment in relapse cases.

Bacterial Diseases

Of the bacterial infections, leptospirosis (Weil's disease, infectious jaundice) is so widespread as hardly to fall in the tropic disease list. It is endemic in Japan. The spirillum is carried by rodents and excreted in their urine. In man the chief effects are swelling and destructive changes in the liver, spleen, kidneys, and lymph nodes. Onset is acute, with fever, headache, nausea, vomiting, diarrhea, and jaundice. Organisms are found in the blood early, and later in the urine for as long as 100 days. An agglutination test and guinea-pig inoculation aid in diagnosis. The possibility of this disease spreading in the United States is undoubtedly present, but uncertain in degree. Treatment is primarily a nursing problem, but may be aided by a specific antiserum.

Relapsing fever, a related disease of wide distribution, occurs in modified form in southwestern states and Central America. It is transmitted by lice or ticks parasitic on small rodents. Clinically the disease resembles the preceding, but icterus and renal changes are less intense and the fever has a definite periodicity, with free intervals of a week or more. Diagnosis is confirmed by finding the causal spirochete in the blood. Treatment by 1 or 2 doses of neoarsphenamine is specific and effective, but should be delayed when a fever crisis is impending. Both relapsing fever and leptospirosis should be subject to epidemiologic control through elimination of the insect vectors in a threatened area with the new DDT preparations.

Yaws, also called framboesia, is a skin disease with constitutional manifestations, caused by a treponema carried by direct contact or flies. It is closely related to syphilis in that it gives a positive Wassermann reaction, is prevented by a previous attack of syphilis, and has marked clinical similarities. The primary lesion usually occurs on the lower extremities, with local adenopathy. There is a secondary septicemia with general adenopathy and fine desquamating papules lasting several weeks. The later tertiary lesions are destructive, with deep scars and deformity; ulcerative rhinopharyngitis is a common development. Organisms should be demonstrable in the primary lesion. Treatment is with neoarsphenamine plus bismuth or carbarsone. Appearance of this disease in the veteran returning from Africa, the East Indies, and the Pacific Islands is presumably possible. Medical standards in this country should prevent any significant spread.

Plague, whether of the bubonic or pneumonic form, should not occur through importation by military personnel. In this connection, however, physicians in this region should perhaps be more aware of endemic plague which occurs among thirty-two or more species of wild rodents in our northwest states, as far east as North Dakota. Human cases have thus far been few and sporadic. When recognized in time, treatment by sulfathiazole has proved quite effective.

Cholera should be mentioned here for sake of completeness, but its introduction into the United States by military personnel is not to be expected. The violence of the infection and brevity of incubation period would surely bring out the infection before the patient disembarked. It is of interest that sulfaguanidine is reported by Huang[18] to have given twenty-one cures in twenty-two patients whom he treated.

Leishmaniasis

Under the term leishmaniasis are grouped three diseases caused by protozoa of special type. Leishmania donovani and one or more related forms are transmitted by species of Phlebotomus or sand fly, and give rise to kala-azar or visceral leishmaniasis. The parasites invade the reticuloendothelial system, causing splenomegaly, hepatomegaly, lymphadenopathy, and occasionally, ulcers of the skin and intestinal tract. The incubation period is usually two to three months. Onset is slow, with irregular fever, visceral enlargement, dark skin, and tendency to dysentery. Blood examination shows anemia, leukopenia, and perhaps the diagnostic parasites, Donovan bodies. Splenic and liver puncture may be resorted to for diagnosis in questionable cases. Therapy is by means of antimony compounds, of which the preferred form is neostibosan or neostam, given intravenously or intramuscularly in graduated doses, one course of ten injections usually sufficing. The disease occurs endemically but fairly widely in Asia, Africa, the Mediterranean basis, and South America. Infection of service personnel may occur, but transmission within the United States is very unlikely as sand flies occur only rarely; they apparently are not found in the Northwest.

Cutaneous leishmaniasis or oriental sore is a maculo-papular, ulcerative, occasionally tuberous skin disease found around the Mediterranean, in India, and South America. Incubation may be as long as three months, and the cutaneous lesions may remain active for over a year. Diagnosis is through finding of intracellular Donovan bodies in ulcer scrapings or biopsy. Treatment is by antimony compounds in smaller doses than those required for kala-azar. Due to its site and nature, this form of leishmaniasis will probably have prompt attention from the military or home physician. In the absence of the sand fly, the disease may be ignored as an epidemic hazard in this country.

Leishmaniasis americana or espundia is limited to Central and South America, and again the sand fly is its carrier. The lesions are flat papules progressing to deep ulceration on the mucocutaneous areas about the mouth, nose, and throat, similar in chronicity to oriental sore. Diagnosis is established by finding the Donovan bodies in ulcer margins. Therapy is satisfactory by use of intravenous antimony tartrate or fouadin.

Trypanosomiasis

Trypanosomiasis is due to protozoan parasites which infest many of the domestic and game animals where they occur. African trypanosomiasis or sleeping sickness has two forms, the West African and East African, due to different parasites, but both transmitted by the tsetse fly. The disease begins with a red nodule termed a trypanosome chancre, which subsides after a few days. The second stage is marked by fever, erythema, malaise, anemia, headache, and lymphadenopathy which particularly involves the posterior cervicals. This stage may last for an indefinite period and may end in death. Most cases eventually go on to a third stage of marked weakness, asthenia, shuffling gait and stupor, the true sleeping sickness. This proceeds to certain death. Diagnosis rests on finding the causative organism in the peripheral blood, or later on in the lymph nodes or cerebrospinal fluid. Early cases respond well to therapy with Bayer 205, given intravenously. For later cases in which the nervous system is affected, tryparsamide must be used; this, however, is effective only in the West African form. In the East African type the disease proceeds more rapidly, and death usually occurs within a year.

Authorities agree that sporadic cases of African trypanosomiasis may occur among American servicemen, and due to the slow course of the disease, may appear after return to the States. The disease must, therefore, be kept in mind, in view of the grave prognosis if undiagnosed and untreated early by specific agents. Spread of the disease in this country would appear impossible in the absence of the tsetse fly.

American trypanosomiasis or Chagas' disease occurs in South America and Central America, where it is parasitic in rodents and other small animals. It is transmitted to man by triatomas, assassin bugs. The initial lesion is often on the eyelid, with edema and conjunctivitis. Trypanosomes appear in the circulating blood, but assume leishmania forms in the muscles. Myocarditis, brain inflammation, visceral cloudy swelling and lymphadenopathy result. The acute stage is marked by fever, edema, splenomegaly, cardiac weakness and arrythmias, and perhaps meningo-encephalitis. The chronic stage is characterized by general visceral enlargement, lymphadenopathy, and irregular fever, with all symptoms gradually diminishing. Death often comes through heart failure. Diagnosis may be established by identifying parasites in circulating blood or smears of lymph gland pulp. Guinea pig inoculation may be necessary. No direct method of treatment has proven effective, but Bayer 205 is reported on favorably. Attacks aimed at the assasin bugs may prove worth while in endemic areas. Like the preceding diseases, American trypanosomiasis may perhaps appear occasionally in service personnel, but transmission within the United States would appear impossible except for the southwestern states, where the assassin bug is advancing from Mexico.

Rickettsial Diseases

Of the rickettsial infections, only two need attention here. Typhus, widespread in the world and prone to increase under wartime conditions, occurs in two forms. The epidemic form is carried by the body louse, infection apparently taking place by crushing of louse tissues or feces into abrasians, rather than through bites. Following a brief incubation period there is onset of sudden, severe headaches, fever, stupor, conjunctivitis, vomiting; later a rash appears, and still later coma, prostration, hemorrhages, ending often in death in twelve to fourteen days by bronchopneumonia, cardiac failure and exhaustion.

The endemic form is transmitted by the rat flea, and due to a slightly different parasite. The disease is less virulent than the epidemic form. Both types may be confirmed in the laboratory by agglutination of X^{19} strain of Bacillus proteus (Weil-Felix reaction). Active treatment of typhus is largely supportive and non-specific. Effective prevention, however, is provided by Weigl's vaccine, a glycerine suspension of infected lice intestines, or by a vaccine prepared in an egg-yolk medium. Due to the short incubation period, the violence of the disease, et cetera, it would appear nearly impossible for any significant number of typhus cases to reach this country in returning armed forces. Furthermore, with sanitary standards existing in the United States, and the potency of our newer insecticide powders, the possibility of a typhus epidemic seems out of the question.

However, a related infection appears of more concern to our present service forces. This is tsutsugamushi fever, or Japanese river fever, a rickettsial infection carried by certain mites in Japan, Korea, and Formosa. A variation of this, called scrub fever, is common in many of the South Pacific islands, and has laid low a fair number of our troops in endemic areas. A small necrotic ulcer initiates the infection, followed by lymphadenopathy, lymphangitis, an eruption lasting six or seven days, bronchial symptoms, muscle and joint pains, prolonged intermittent fever, and often delirium. Fatality rate is said to be about 15 per cent. The disease can be identified by agglutination of the OXK strain of B. proteus. Like epidemic typhus, treatment is symptomatic and supportive only. No preventive therapy has been announced.

Virus Infections

Coming to virus diseases, two seem worthy of consideration. Yellow fever, a severe epidemic and endemic infection carried by various mosquitoes, particularly Aedes egypti, is widespread in western Africa and certain parts of Central and South America. It has invaded North America more than once. In the human body the virus attacks the capillary lining, with virusemia and visceral necrosis. The clinical picture is dominated by fever, jaundice, slow pulse, hemorrhages, and severe kidney damage. Death occurs in 10 to 60 per cent between the sixth and tenth days. Diagnosis can be proven by a mouse protection test. There is no specific treatment of the active case, but excellent protection is provided by vaccination with an avirulent neurotropic virus which is good for four years. Anti-mosquito measures in endemic regions and quarantine procedures in nearby ports have proved of value. Due to fairly rigid observance of such methods, it is believed that yellow fever should not further threaten North America.

Dengue, breakbone fever, is another virus infection carried by Aedes; it occurs in the Pacific, Near East, South America, West Indies, and occasionally in southeastern United States. After a short incubation period the patient complains of joint pain, headache, erythema, fever, and severe general malaise. There is a brief remission, then a return of symptoms, with skin rash, desquamation, and leukopenia. Diagnosis is presumptive, based on epidemiologic factors. Treatment is symptomatic. No preventive is thus far available. Though troops in the South Pacific have suffered dengue epidemics at various places, transmission in this country would generally be impossible due to absence of Aedes.

A number of other tropical maladies—leprosy, sprue, the less common virus, rickettsial, and parasitic diseases might be discussed here, but do not appear pertinent to the subject as not posing significant hazard to this region.

Conclusion

The accompanying table summarizes the likely tropical disease hazards in the Northwest.

Disease	*Hazard in Returned War Veteran*	*Hazard in Others*
Malaria, Tertian (Vivax)	††	†
Aestivoautumnal (Falciparum)	†	?
Quartan and Ovale	?	0
Ascariasis	†	?
Hookworm	†	0
Filariasis (Wuchereria Bancrofti)	†	0
Other types	†	0
Tapeworm	?	0
Echinococcus Cyst	?	0
Schistosomiasis, Urinary or Intestinal	†	??
Other Fluke Diseases	?	0
Bacilliary Dysentery	†	†
Amebiasis	†	†
Leptospirosis	†	?
Relapsing Fever	?	0
Yaws	†	?
Plague	0	0
Cholera	0	0
Leishmaniasis	†	0
Trypanosomiasis	†	0
Typhus, Epidemic	0	0
Endemic	?	?
Tsutsugamushi Fever, Scrub Fever	0	0
Yellow Fever	0	0
Dengue	0	0

Two general points of caution mentioned by Guldseth[15] and various writers should be noted in dealing with patients who have been in tropical and oriental countries. The first is that malaria, yaws, and a number of other tropical infections may cause positive Wassermann, Kahn, and Kline reactions, leading the careless diagnostician to a wrong conclusion. The second is that returning personnel must be carefully checked by history and blood smears before use as blood donors, if accidental transmission of tropical disease parasites is to be avoided.

In general, the practicing physician or surgeon can prepare himself in four ways to meet the tropical disease threat in the postwar years. First, he should know what diseases are likely to or possibly can appear. Second, he should learn the habit of including tropical diseases in his bedside diagnosis, and not merely leave them as abstract concepts on his bookshelves. Third, he might well see that his laboratory technicians are alive to the special studies so essential in this line of work. And fourth, he might determine where special consultants can be found if need should arise.

In this connection, it is of interest to note that medical educators are aware of the need for wider knowledge of tropical medicine. There are plans for broader courses in a number of medical centers, and for the formation of some type of consultant bureau. Further, concentrated courses have been and are being given to selected groups of physicians under the auspices of the American Association of Medical Colleges, the Co-ordinator of Inter-American Affairs, the Surgeon General, and other agencies, the schedule including a period of field work in Central or South America.

Thus, there is hope that America's wider ventures in international relations may bring new health to other peoples, while maintaining reasonable safety for our own.

FACIAL INJURIES

JEROME A. HILGER, M.D.
Saint Paul, Minnesota

THE two immediate concerns in a facial injury are the maintenance of the airway and the control of bleeding.

The tongue must be maintained in its forward position by placing the patient face down. If necessary direct traction is made on the tongue. This is rarely necessary in a conscious patient, except when the symphysis of the mandible and the floor of the mouth are badly disrupted. Bleeding can usually be controlled by pack and manual pressure.

If a trachectomy appears to be needed it should not be postponed until it becomes a desperate and hurried measure. It should be done in an orderly manner under local anesthesia with the trachael opening placed well below the level of the cricoid cartilage. An anxious and hurried tracheotomy is necessary more often because of the surgeon's procrastination than because of immediate urgency at the moment of the injury. When the decision is in doubt one should lean in the direction of commission and create a tracheal opening. It provides an assured airway and a fine means of pulmonary drainage and the patient has a tranquil postoperative course which diminishes the need for sedation and assures one of the patient's co-operation in combating atelectasis.

Shock is not a common feature of facial injuries unless they be extensive and involve vessels of good size. Plasma is a useful immediate measure for combating shock when it exists but the blood volume should be restored at the first opportunity by whole blood transfusions.

It is not unusual in extensive injuries of the face and jaws to have associated cranial involvement. After establishing an airway and restoring the patient's circulatory efficiency one should therefore perform a neurological examination and establish the presence or absence of intracranial involvement.

In severe smashes of the central third of the face which occur as a result of the forward motion of the face against some immovable part of a vehicle or airplane a compression fracture of a vertebra is a common associated injury. It is well to bear this fact in mind when one examines the rest of the skeletal system for injuries.

The facial skeleton when considered surgically can well be divided into two main portions: the mandible, and the bones comprising the middle third of the face.

One has two objectives in the care of a fractured mandible. The first is to get bony union and the second is to obtain good dental occlusion. To accomplish these one sets the teeth of the mandible into proper occlusion with the teeth of the maxilla and fixes them there. The means of fixation vary with different oral surgeons but so long as the fixation is firm and the position is good the results tend to be satisfactory.

There are certain fractures of the mandible that deserve special consideration. Of these, the first perhaps is a fracture of the condyle of the mandible. In general, because of the inaccessibility of the condylar portion of the mandible it is impossible to restore its alignment with the main body. An accepted method of treatment of such fractures is simple splinting of the mandible during the period of pain and swelling. Splinting is done in proper dental position by occluding the lower teeth to those of the maxillae. After the initial period of pain has passed motion is encouraged and nonunion at the fracture site is established. A method of open reduction to re-establish proper alignment of these fractures may be used, but the first and simpler method has seemed adequate.

Since the teeth are the means of both fixing and positioning the mandibular fragments, a special problem arises when a posterior mandibular fragment with muscular attachments is separated from the remainder of the tooth-bearing portion of the mandible by a fracture line posterior to the last tooth. This fragment, often referred to as the edentulous posterior fragment, is comprised of the vertical ramus of the mandible and any of the horizontal portion extending forward to the fracture site. There are different means of fixing this fragment in position during the

---

Presented before the Saint Paul Surgical Society, November 21, 1945.

healing period. None of the means is applicable in all cases. In some cases a controlling wire is inserted at the posterior margin of the vertical portion of the mandibular ramus and is let through the skin posteriorly beneath the lobe of the ear to a hook descending from a plaster head cap. In others a small half-round bar is fashioned and secured to the arch of the lower teeth. A posterior extension of this bar can be bent and angled so that its sharp terminal end can be set into the posterior fragment of the mandible much in the manner of a skeletal pin, thus maintaining the relation to the anterior fragment. It is in cases of the edentulous posterior fragment that external skeletal fixation has its widest application. Paired pins are inserted into the mandible anterior and posterior to the fracture line. The couplets are then connected across the fracture site by a firm bar. In using this technique we have not given the mandible free range during its entire healing period. During the first weeks when union is being established we have assisted the external fixation in its support of the fracture line by fixing the mandible to the maxilla by inter-maxillary wires.

A third major problem in mandibular fractures arises when there is considerable loss of substance of the bone and re-establishment of full continuity and alignment is not possible by simple means. This is the type of mandibular injury often seen in gun shot or shell fragment wounds. Large sections of the mandible are extensively comminuted and fragmented and pieces are displayed into the soft tissues of the floor of the mouth or even down into the soft tissues of the neck. When such injury occurs in the symphysis area and the fragments are of considerable size and driven posteriorly into the muscles of the tongue it is possible to retrieve them by direct traction on the fragments by means of small wire loops inserted through dental drill holes, and attached with elastics to an anterior bar replacing the former position of the mandible. This bar is supported in its place by cementing it firmly to the most anterior viable teeth on each side of the mandibular stumps. Rubber band traction applied over a period of several days will often draw forward the fragments with their muscular and periosteal attachments into a semblance of order in the anterior symphysis area. In the region of the horizontal ramus where this extensive comminution occurs from a penetrating type of wound, it is surprising how frequently the multiple fragments displaced a considerable distance from their proper location will, over a period of several days, due to the retraction of periosteal attachments and shreds which have extended out into the soft tissues with the bone fragments, replace themselves into their original alignment. It is generally impossible to restore these multiple fragments to their original position by manual traction and one must be extremely careful in handling the fragments that the single remaining periosteal attachment is not destroyed. Often only a single nutrient vessel traverses the attachment and means the difference between a live bone fragment and a squestrum. The portions of mandible on both sides of a large area of loss such as has just been described must both individually be supported in proper relation to the teeth of the maxillae. Fixation must be maintained for many months to give the periosteal shreds and the remaining bone fragments full opportunity to lay down new bone and make an abutment at each end of the fracture site. In dealing with areas of extensive mandibular loss, silver cap splints are made with a fine technique to completely crown the residual teeth of the mandible. These are cemented in place and thereafter give a firm means of attachment to all the types of bars and supports which may be required for fixation.

Injuries below the frontal bone and above the mandible are referred to in general as injuries of the middle third of the face. The bones comprising the middle third of the face include the maxillae, the nasal and malar bones, and the ethmoid bone. These bones have suture lines in common with the frontal bone. When injury causes fractures extending across this line, the case often becomes a neurosurgical problem also. Fracture of a single one of these bones often occurs in the simpler types of injury. The simple reposition of a single fractured bone of the middle third creates few problems. There are many acceptable techniques for each of them.

When the malar bone fractures, it usually does so at its articulations with the frontal, the maxilla, and the temporal bone and the crush is usually medialward into the maxillary sinus. Occasionally the bone itself is comminuted. For the simpler type of depressed malar fractures we have used the temporal method of reduction often known as the Gilles method. In it an elevator is introduced beneath the temporal fascia and downward beneath the zygomatic arch. This allows firm leverage on the bone for elevation.

An occasionally badly comminuted fracture of the malar bone requires intra-sinus elevation. An approach is usually made through the canine fossa. Support is given to the comminuted fragments by a firm pack placed in the maxillary sinus after elevation. This method compounds the fracture, however, and damages the maxillary sinus mucosa, and the pack must be left in place for several weeks thus exciting a fairly marked reaction in the cheek. It should not be used in the reduction of the simple type of malar fracture.

We have used this intra-sinus method of elevation in some fractures of the malar bone seen as late as six to eight weeks after injury. Since it is the nature of the malar bone to heal very rapidly, malposition becomes firm after but a few weeks. Therefore, when a badly depressed malar fracture with loss of orbital support is seen after several weeks it is more than likely that simple means of elevation will not suffice. One is faced with the problem of accepting a deformity for later correction by transplant methods of fascia, cartilage, or bone or of re-fracturing the malar bone and elevating it into position. The latter method of correcting the deformity is preferable when it can be applied. After refracturing and repositioning, the bone must be fixed in its proper position for a long period of time. Fixation to a headcap by external means is best. An external pin couplet is a very satisfactory means of fixation and allows control of the malar bone for any type of manipulation to adjust its fineness of position postoperatively.

The nasal bones, due to their prominent position are, perhaps, the most commonly fractured bones of the body. The fractures range all the way from simple malposition correctable by elevation and thumb pressure to cases of extreme comminution and depression with disruption of the entire ridge support of the nose. The latter type is often associated with maxillary and ethmoid labyrinth fractures and with extensive lacerations of the soft tissues. In these latter cases the interior of the nose should be carefully repaired with replacement of the turbinates into their normal position and suture of the mucosa of both the septal and the lateral walls of the nasal space in an edge to edge manner. The nasal septum should always be replaced in a midline position. The Asch forceps is a useful instrument for gripping the septum and rocking it into place. The function of the nose and the appearance of the face should be equally important objectives in the reparative process. When the nasal interior is agglutinated into a mass of adhesions and scar tissue it can later be redeemed as an airway only through extensive sacrifices of intra-nasal tissue.

It is difficult in cases of severe comminution of the nasal bones to maintain the dorsum in its normal, ridgelike position during healing and some external means must be used to effect it. Perhaps the simplest method is the use of through and through silk or steel wire sutures placed at the superior and the inferior limits of the nasal bones and tied on both sides over a fashioned lead plate. This prevents broad spread of the comminuted nasal bone fragments and gives a tenting effect to the ridge. A more complex but more effective external appliance is required in some instances. It operates by means of two curved bars descending from a headcap and terminating in wire hooks inserted upward high into each nasal space. These are tensed and locked to give proper forward traction.

The ethmoid labyrinth when it is bulged laterally into the orbital spaces must be compressed medialward into its normal position by deep pressure at the inner angle of both orbital spaces. Simultaneous elevation of the nasomaxillary bone mass helps narrow the ethmoid. When x-ray reveals spicules of ethmoidal or frontal bone turned in an intracranial direction, or when there is evidence of a cerebrospinal leak, the services of a neurosurgeon are requested. The facial injury becomes a secondary matter. The manipulation of the facial bones should be deferred until the dural opening is well sealed. If it seems advisable, the soft tissues of the face may be repaired under local anesthesia in the interim.

When the maxillae are fractured, the problem of dental occlusion again arises. In those instances where the mandible is not also fractured one borrows the mandible to use as both a splint and a positioning agent by applying intermaxillary wires to occlude the teeth of the maxillae to the mandible. Because of the weight of this combined mass, one must then support the whole lower face in order to keep it in normal relationship with the upper half of the face and head. There are many methods of attachment of the maxillary and mandibular mass to headcap supports to prevent sagging of the lower portion of the face. Here again the silver cap splint cemented to the teeth and attached to a plaster headcap with screw plates and bars lends itself to a satisfactory solution of the problem. Fine wires attached to the intermaxillary loops and run upward through the soft tissues of the cheek to a headcap bar can also be used to support the lower facial mass. The pull of such wires is entirely upward and if there is loss of bone substance in the middle third fracture a shortening of the vertical dimension of the face can result from this method. Vertical bar support which controls upward as well as downward movement is preferable in many cases. Rigid bars are applicable in this manner from a headcap appliance to the cap splints cemented to the teeth, or to an arch bar wired firmly to the teeth, or to external skeletal pin couplets inserted into the mandible.

Fractures of the bones of the middle third of the face tend in general to heal rapidly. Early and proper positioning therefore is imperative. Once healing in malposition has been effected it requires a major procedure to correct the deformity. Occlusion may be restored only by the sacrifice and grinding of teeth, and the use of cartilage or bone implant may be necessary to correct the contours of the face. Attention should be given to the facial injury as soon as the patient's general and neurologic condition permits. Improper healing in this area can result in gross malformations as well as in disabling malfunctions of the nasal and dental apparatus.

In the majority of fractures of the facial bones manual traction is adequate for replacement of the fragments. It is not uncommon, however, in fractures of the malar, the maxilla, or the mandible that application of average strength to the manual reduction is not adequate to restore the alignment of the parts. The use of steady traction is as useful in facial fractures as it is in fractures of bones of the other parts of the body. Elastic traction over hooks wired to the teeth and extending from upper teeth to lower teeth is frequently employed in reduction of mandibular and maxillary fractures. A severely impacted fracture of the malar bone can also be replaced by gradual rubber traction to a headcap appliance. In some very late impacted fractures of the malar or maxilla, however, elastic traction to a headcap is not adequate. There is a limit to the amount of pull which can be exerted from a headcap apparatus. When one has no success after twenty-four or forty-eight hours, other traction means must be resorted to. By means of perforating wires inserted into the infra-orbital rims or into the alveolar process of the maxilla or by means of couplet pins inserted into the body of the malar bone one can get a firm grip upon the structure which will withstand any ordinary pull over a long period of time. It is a simple matter then to construct a bed frame with pulleys and to attach a weight traction of several pounds to the wire loops or pin couplets. The head is braced into position with sand bags and one has all the necessary latitude in the direction and in the strength of pull. Most impacted fractures and those united in malposition beyond any other means of reduction will give with this kind of pull. Once the bone is restored to normal position it will either maintain itself there freely or it can be maintained by support to the headcap. The metal cap splint cemented firmly to the upper teeth lends itself admirably to this type of traction for disimpaction of the maxilla.

The soft tissue portion of the facial injury is often more readily repaired than is the injury to the skeletal parts. It is preferable to make the primary repair a meticulous and thorough procedure. To this end, it is best to cover the injury with sterile dressings until the patient is resuscitated and his airway established. He can then be transported to the place where his complete facial repair can be done.

The wound should be cleansed with saline irrigations and all the debris removed manually. In the face the soft tissue debridement can be done very conservatively because of the fine blood supply. Flaps and pedicled parts which in other portions of the body must inevitably be lost will often maintain their viability in the face. All completely free fragments of bone should be removed from the depts of the wound before the soft tissues are joined. Those fragments of bone which have even small attachements to the periosteum will usually remain viable and take part in the general skeletal healing if postoperative infection is avoided. Foreign bodies should be removed from the depths of the wound.

In uniting the soft tissues the buried suture should be held to the minimum requisite with maintaining the position of the flaps. Fine skin suture should be used for the skin edges and tension on these sutures should be avoided. They should usually be removed in three days. With careful hemostasis, drains are rarely needed and often are ill advised. In handling the soft tissue flaps the use of forceps should be avoided as much as possible. It is preferable to handle the flaps with the fingers or gauze. A great deal of tissue can be bruised in a long reparative procedure through the pinching of thumb forceps. When venous congestion and edema of the injured parts occurs postoperatively, the tissues tend to distort, healing is delayed, and a fine culture medium for postoperative infection is present. It is best combated by application of a pressure dressing to the postoperative wound. Healing is accelerated by the prevention of edema. When external fixation appliances are attached to the face, the application of a pressure bandage is extremely difficult, and it is not possible to wind an elastic bandage about the face. However, in circumstances such as this adequate pressure can be maintained by fashioning a portion of a rubber glove with vents and slits for the external appliances and with strings or straps extending posteriorly to tie behind the head. When large pedicled flaps of soft tissue have been formed by the wound the prevention of edema may make the difference between maintaining the viability of these flaps or losing the flaps through inadequate circulation.

The face is a sort of surgical paradise. It tends rarely to become infected. Infection can be a catastrophe, however. To prevent postoperative infection several points must be stressed. First, is the assured removal of all irritating foreign bodies whether they be completely separated fragments of bone, fragments of clothing, fragments of rock and earth, or of other material. The second important factor is the fixation of all movable fractured parts. A continued breaking down of fresh, new granulation tissue about fractured bone ends favors infection. The prevention of postoperative edema robs potential bacterial invaders of their favorite growth medium. When the wounds extend intra-orally as do so many of the facial wounds, mouth hygiene is of importance. All intraoral lacerations should be sutured with meticulous care. Mouth organisms can and usually do cause a very foul type of suppurating wound unless controlled. Normal saline is a most effective and non-irritating cleansing solution for use in the mouth. It should be used frequently throughout the day. The cleansing is followed with a light dusting of all intra-oral lacerations with a combination of penicillin and sulfanilamide powder. Severely wounded patients are given a routine post-injury medication of penicillin and oral sulfadiazine. In moderately severe wounds penicillin alone is often used. Penicillin solution is trickled into the lines of laceration after all reparative procedures. It is very desirable in all badly comminuted fractures that absolutely no infection supervene because the viability of a great number of small bone fragments depends upon just one nutrient vessel extending through its shred of periosteal attachment. Loss of this vessel means loss of the fragment of bone and in many extensive injuries loss of but a very few fragments of bone results in non-union.

Anesthetic choice is not easy in some types of face and jaw injuries. Some soft tissue work and some skeletal repair such as mandibular realignment can be done with local anesthesia or with morphine premedication. More extensive injuries require general anesthetic. This is particularly true when the wound extends into the airway and considerable bleeding is bound to occur during the surgical procedure. In such circumstances it is obvious that the airway must be occluded and intratracheal anesthesia either through the nasal or oral routes is preferable. When a tracheotomy tube is in place, most of the anesthetic problem is solved. We frequently use a combination of intravenous pentothal and inhalation nitrous oxide and oxygen. When working in or near the larynx, superficial application of a dilute cocaine solution combined with this anesthesia circumvents the laryngeal reflex.

The postoperative care of facial injuries is as important as the reparative procedure. It is important to maintain a clear airway and a dry lower respiratory tree. Since anesthesia need not be deep the patients awaken early after surgery and are encouraged immediately to cough and hyper-ventilate. The head is elevated as early as is possible to circumvent edema of the facial structures. This puts an added load upon the cilia in emptying the tracheobronchial tree, but

THE Rh FACTOR

KANO IKEDA, M.D., E. M. KASPER, M.D., and ROBERT ROSENTHAL, M.D.,
and
Members of the Obstetric and Pediatric Services of the Chas. T. Miller Hospital
Saint Paul, Minnesota

Brief Review

Kano Ikeda, M.D.

The Rh factor is, at the moment, one of the most discussed medical subjects appearing in the current medical literature. It is, perhaps, one of the most important discoveries of the present decade. Therefore, a brief review of the subject, and the presentation of a summary of the autopsied and recovered cases which came under my observation seem timely.

For many years there had existed in the minds of the investigators a growing suspicion, bordering on a conviction, that one of the major causes of fetal and maternal morbidity might, somehow, be linked with an incompatibility between the blood of the mother and that of the fetus, and a resulting antigen-antibody reaction. More recently, a few attempted to explain the pathogenesis of erythroblastosis fetalis on the same basis. Simultaneously, reports had appeared of the unexplained intragroup hemolytic reactions occurring in individuals who had received repeated transfusions, and in mothers who had given birth to erythroblastotic or macerated babies. In some of these cases, the presence of an agglutinin, which was thought to be responsible for the reaction, was actually demonstrated.

In 1940 came the announcement of the epochal discovery by Laudsteiner and Wiener of the Rh factor in blood, a Mendelian dominant, in about 85 per cent of human beings, which is capable of producing immunization in the remaining 15 per cent of individuals. Wiener was now able to explain the cause of the severe hemolytic reactions which occurred in patients who had received transfusions of homologous blood. Later in the same year, Levine and his co-workers published an observation that the sera of women who had had repeated miscarriages or abortions contained agglutinins shown to be related to the Rh factor. The following year, Levine, Katzin and Burnham published, in the *Journal of the American Medical Association*, an article entitled, "Iso-immunization in Pregnancy: Its Possible Bearing on the Etiology of Erythroblastosis Fetalis." This paper and several others which closely followed clearly established their theory that the genesis of erythroblastosis fetalis in a great majority of instances is related to the immunologic reaction due to the Rh factor between the mother and the baby. In spite of the importance of this discovery in clinical medicine, the medical profession in general was, at first, slow to grasp its significance. The clinical laboratory, too, was not immediately awakened to the importance of Rh determination in clinical medicine. The obstetricians and the pediatricians became more and more interested in the subject, only as they came in contact with clinical cases of their own, in which the Rh factor played a role. Only in recent months the interest of the physicians in general seems at last to have become more universal.

Today, thanks to the diligent and fundamental investigations of such men as Wiener, Levine, Diamond, Davidsohn and others, we have come to undertsand a great deal more about the Rh factor. At the same time, we have also come to realize that the subject has been, in a way, made so complex and complicated by the very same men who have been publishing new data as they come into their possession, sometimes too prematurely, that the rest of the medical profession has been left too bewildered to grasp the important theoretical and technical considerations which form the basis of the clear understanding of the subject.

The determination of the Rh factor and its related sub-types, the laboratory diagnosis of erythroblastosis fetalis and of the intragroup hemolytic reaction, therefore, constitute a complicated immunologic problem and their proper interpretation requires the understanding of genetics. The average clinical laboratory is neither equipped nor staffed to render complete immunologic service or genetic interpretation of the sub-

---

Presented at the General Medical Staff Meeting of the Charles T. Miller Hospital, Saint Paul, Minnesota, November 6, 1945.

ject which is yet undergoing further exploration by the fundamental investigators.

Fortunately, however, a few important practical observations along with the original basic discoveries can be and are being made which apply to everyday practice with satisfactory results and a degree of assurance. I shall discuss the laboratory phases of this complicated subject in a form of questions and answers, in so doing, purposely avoiding the use of genetic terms for the sake of simplicity.

1. What is the Rh factor? The name was coined by Wiener and Laudsteiner, the discoverers, and derived from the first two letters of rhesus monkey, whose blood was injected into rabbits to produce an anti-rhesus serum, which was found by them to cause agglutination of the blood of about 85 per cent of white individuals. The blood of these 85 per cent of people is known as Rh positive, because the anti-Rh serum causes its agglutination, while the blood of the remaining 15 per cent is known as Rh negative and is not agglutinated by the anti-Rh serum. The Rh positive is a Mendelian dominant while the Rh negative is a recessive.

2. What is the one most important basic question involved in this entire subject? The immunization of the Rh negative person by the blood of the Rh positive individual with resulting antigen-antibody reactions which may occur actively or passively, depending upon how the victim is sensitized.

3. What, then, makes the subject so complicated? Whereas, in the beginning, there was only one anti-Rh serum for the determination of the Rh factor, we now have three types of anti-Rh agglutinins, namely, anti-Rh$_0$, anti-Rh′, anti-Rh″, with occurrence of the last two, separately and in association with the first, giving rise to two additional anti-Rh serums, anti-Rh$_0$ + anti-Rh′ or anti-Rh$_0$′ and anti-Rh$_0$ + anti-Rh″ or anti-Rh$_0$″. Thus, we now have five major varieties of anti-Rh serums and their corresponding Rh factors instead of only one, and these five Rh factors give rise to eight types of human blood. Therefore, to make the complete Rh factor determination, we should have the three anti-Rh serums mentioned. However, they are not as yet available for routine use. The testing serum we now use contains anti-Rh$_0$ and anti-Rh′ agglutinins which gives about 87 per cent positive reactions on the bloods of the white individuals in New York City. Then we have the tedious procedure of titration for anti-Rh agglutinins, and the problem of dealing with the so-called "blocking antibodies" which interfere with the titration. We are also confronted with Hr factor, with whose nature we are not as yet quite familiar.

All of the procedures are complicated and exacting, requiring the attention of an expert technician, specially trained to do the job.

4. Briefly, what is the mechanism whereby the baby develops erythroblastosis fetalis? In 90 to 95 per cent of the cases, the father is Rh positive and the fetus is also Rh positive while the mother is Rh negative. The Rh positive blood of the fetus enters the Rh negative mother's circulation through the placenta and in time, causes in the mother the production of strong anti-Rh agglutinins. These agglutinins, in turn, enter the fetal circulation and cause a true hemolytic anemia through the destruction of the fetal blood and stimulate extra-medullary erythropoiesis. (See question 7.)

5. Are all Rh negative individuals easily sensitized by the Rh positive blood? No, only one in twenty-five to fifty are readily sensitized. Others may require several or many transfusions or pregnancies to become sensitized. The incidence of frank cases of erythroblastosis fetalis is, therefore, much smaller than generally anticipated, theoretically estimated to be one in from 200 to 350 pregnancies. Actual figures are still smaller. Levine estimated about 0.1 to 0.2 per cent of all pregnancies.

6. Can Rh negative mothers continue to have normal babies? The first child is expected to be normal provided the mother has had no transfusions with Rh positive blood before becoming pregnant. Several subsequent babies may be normal, depending partly upon how sensitive the mother happens to be and partly upon some yet unknown factors. Such mothers may have a normal baby again if the intervals between the pregnancies are long enough, that is, three to five years or longer, to let the anti-Rh agglutinins from previous pregnancies disappear. (This may be a theoretical wishful thinking, especially where the father happens to be homogygous Rh positive.) A normal Rh negative baby may be born of a sensitized mother, provided the father happens to be heterozygous Rh positive, in which case he has a 50 per cent chance of having normal Rh negative babies. The father may be considered

heterozygous if any of his blood relatives, namely, any one of the parents, brothers, sisters or children, should happen to be Rh negative. (It is also stated that the father is homozygous if his cells are agglutinated by Rh', Rh_o anti-sera and by anti-Hr serum.)

7. May an Rh positive mother have an erythroblastotic baby? Yes, approximately 5 to 10 per cent of the mothers who have given birth to babies with erythroblastosis fetalis have been found to be Rh positive. This can be best explained, in most instances, as due to the presence of some of the sub-types of the Rh factor in the mother while other sub-types are present in the blood of the husband and in the blood of the fetus. In other instances the group A or B blood may act in the identical manner as the Rh factor in the baby's blood and cause the production of anti-A or anti-B agglutinins of sufficiently high titres in the group O mother to cause the disease. Some cases are also probably due to the Hr factor incompatibility. That is, in a few cases of Rh positive mothers of erythroblastotic babies, the agglutinins were found which reacted with all Rh negative persons and with some Rh positive persons. The Rh positive persons that reacted with this blood were heterozygous Rh positive, having an Rh negative recessive factor.

8. Can the presence of the anti-Rh agglutinins be demonstrated in every case? No, the titre may not be strong enough to be demonstrable. Occasionally, the "blocking antibodies" or the inhibitory substance in the serum to be tested may partially combine with the test Rh positive cells to neutralize the reaction. The technique has now been developed to eliminate this interference so that the titre of the anti-Rh agglutinins may be determined.

9. What are the "blocking antibodies"? They are the special Rh antibodies, incomplete antibodies, found in the sensitized maternal blood (along with the anti-Rh agglutinins) which combine with Rh positive cells, without causing agglutination, thus "blocking" or inhibiting the agglutination of the cells by the anti-Rh agglutinins. They are also known as the inhibitory substance.

10. Can the presence of the blocking antibodies be demonstrated? Yes, on the titration of the anti-Rh agglutinins, if agglutination of the testing cells occurs not in lower dilutions but only in higher dilutions, the presence of the blocking antibodies is suspected. Either the simple slide test of Diamond or the more complicated conglutination test of Wiener is employed to demonstrate them.

11. What is the Hr factor? It is difficult to define it because not enough is known about it. The symbol Hr represents the factor which is opposite to Rh because it is present in Rh negative blood. The Hr antibody clumps the blood from all Rh negative and heterozygous Rh positive persons. The failure of an Rh positive blood to be clumped by it indicates that it belongs to a homozygous Rh positive person. (This is still disputed by some authorities.)

12. Does the high titre of the anti-Rh agglutinins mean a bad sign for the unborn baby? Usually, yes, but not necessarily. The anti-Rh agglutinins may be carried over from previous pregnancies, apparently, with little effect on the unborn baby if it happens to be Rh negative.

13. Is early induction of labor or a cesarean section indicated in every case of mothers who have previously given birth to an erythroblastotic baby or babies or who are merely Rh negative? No. The Rh negative mothers who have had no history of miscarriage or of having been pregnant previously, should be left alone; only the development or rise in the anti-agglutinin titre should be watched. Even those mothers who have the history of having given birth to erythroblastotic babies or having had miscarriages or abortions, should better not be subjected to the risk of a cesarean section promiscuously. The insult of prematurity is usually a little bit too much for the babies already affected by erythroblastosis. If the titre of the anti-agglutinins should suddenly and sharply rise or fall toward the end of pregnancy, some investigators advocate a cesarean section. However, the low titre does not necessarily mean a mild form of erythroblastosis. A sudden drop in titre toward the end of pregnancy may mean hydrops of the severest form.

14. What would be the first step in treating a newborn erythroblastotic baby? The first step would be to do a blood count. If the count shows 3,500,000 of erythrocytes or higher, immediate transfusion is not necessary. Watch the count at frequent intervals. At the same time, have a Type O, Rh negative donor ready, if possible. Give Type O, Rh negative blood, approximately 10 c.c. per pound body weight, intravenously, and if urgently indicated, possibly through the umbilical vein. If an Rh negative donor is not available,

the mother's blood may be given. Such blood should be citrated, washed twice in saline and given resuspended, preferably in compatible plasma, or in concentrated form. In mild cases, one such transfusion is usually sufficient. The sooner the transfusion of Rh negative blood is given, the more effective is the treatment. Then, the mother's milk should not be fed the baby. The antibodies have been demonstrated in the mother's milk. The baby should be kept in an oxygen tent. If Rh negative donors are not available, compatible Rh positive blood may have to be given as an emergency measure. While Rh negative blood is said to survive for periods up to three months in the baby, Rh positive blood is known to be eliminated within four to five days. This is due to the demonstrated fact that the mother's anti-Rh agglutinins are present in the baby's circulation as long as twelve to fourteen days after birth. The essence of the treatment is, therefore, to keep up the oxygen supply to combat anoxemia. Plasma and glucose can be safely given as well as oxygen.

15. In what other conditions does the Rh factor play a vital role? In all cases of blood transfusion, the determination of the Rh factor has become as important as the routine typing and cross-matching of bloods of the recipient and the donors. This is imperative, especially when repeated transfusions are to be given to one recipient. Should he be Rh negative and the donors positive, precisely the same situation occurs as in pregnancy with the stimulation of anti-Rh agglutinins and a resulting hemolytic reaction in the recipient.

I wish now briefly to present a few pertinent data from the cases of erythroblastosis fetalis in which autopsy was performed.

Tables I and II give the summary of the findings in the thirteen cases of erythroblastosis, seven in the icterus gravis type, four of the hydrops type and two macerated babies. I wish to particularly call your attention to the last column of each group which gives the average figures. Your attention is directed to the following observations. Prematurity appears to be common, thus adding to the risk of the baby. The hydrops babies were born dead, or lived for one hour or less, while the icterus cases lived for an average duration of 34 hours; proper and adequate treatment might have saved some of these babies. The Rh factor was positive in all the babies tested. The liver was definitely enlarged, an average weight of 145 grams against the normal weight of 118.5 grams in the icterus series, and 191

grams against 129 grams in the hydrops group. The enlargement of the spleen is most striking in most of the cases. In the hydrops group an average weight of the spleen was 49 grams (including the one of extraordinary size, 135 grams, exclusive of which, the weight was 21 grams) against the normal of 8.8 grams. For the icterus group, the weight was 26 grams against the normal of 8.2 grams. Extramedullary erythropoiesis was observed in all or most of the visceral organs in varying degrees. Iron pigments were demonstrated in the liver, whenever stained for them. The brains were not examined for kernicterus.

Maternal histories revealed the following: The Rh factor on eleven mothers was negative, one positive, and one undetermined. Of the thirty-four dead babies of the thirteen mothers, five were hydrops (two stillborn), seven macerated (four by the same mother), three premature stillborn (no reference made as to erythroblastosis), one stillborn with toxemia, one unknown, one hysterotomy at fourth month, and four miscarriages. One of the women, thirty-five years of age, had four babies with icterus gravis and one hydrops and one stillbirth at the eighth month. Two of the five hydrops babies were delivered by a cesarean section. The mother of one of these two babies showed a low anti-Rh agglutinin titre and blocking antibodies, and a cesarean section was performed with a hope of saving the baby. The baby only gasped for breath and expired. One of the icterus babies had a syphilitic mother. The roentgen diagnosis of the baby's long bones was given as possibly syphilitic. The differential diagnosis was difficult. However, the microscopic findings of the visceral organs were those of erythroblastosis fetalis.

The first baby recorded here which came to autopsy in February, 1937, will be reported more fully. I believe this is the first case of erythroblastosis fetalis recorded in the Department of Pathology of the University of Minnesota. The baby was delivered of a multipara, aged forty-four, who had two previous pregnancies, one dying at the age of ten days, and the other a stillborn with icterus, and who had been given anti-syphilitic treatment because of jaundice and death of the second baby, although her Wassermann was negative. The present baby showed a moderate degree of jaundice and a universal edema of the body with a marked distention of the abdomen which was first thought to be due to the distended urinary bladder. When catherization failed, the abdomen was tapped, which revealed free blood in the cavity. At autopsy, the peritoneal cavity was filled with blood which had originated from a ruptured spleen weighting 135 grams. In this case, too, the question of congenital syphilis was at first entertained. Several of the mothers were suspected of having or actually had a hydramnios, and the placenta was swollen and heavy, weighing two to four times the normal weight.

Since 1939, we have recorded in this hospital approximately fifteen clinical cases of erythroblastosis fetalis of the icterus gravis type with complete recovery. Actually, I suspect that there must have been an equal number of undiagnosed cases, particularly among the stillborn who did not come to autopsy and whose mother's Rh was not determined. Several severe cases were encountered. Baby S. had 139,000 nucleated cells per cubic millimeter at birth (104,000 erythroblasts and 35,000 cells of the myeloid series) in June, 1939, and developed the most intense and sustained jaundice for more than five weeks. He developed a few petechiae, was lethagic and cyanotic. His hemoglobin dropped from 82 per cent to 30 per cent within a week. During the first eight days, four intramuscular injections of 28 to 35 c.c. of blood were given without appreciable improvement. On the ninth day, 100 c.c. of blood was transfused. The hemoglobin began to rise gradually up to 53 per cent on the twenty-fifth day. He was discharged on the thirty-second day, still somewhat jaundiced and anemic. Today, at the age of six, the baby appears normal and healthy. Baby G. was delivered by a cesarean section prematurely in November, 1940. It was sluggish and soon developed a deep jaundice. There were 48,000 nucleated cells per cubic millimeter. The hemoglobin was 48 per cent which gradually fell to 39 per cent, in spite of two intramuscular injections of 15 and 10 c.c. of blood and two injections of 20 c.c. plasma during the first week. A transfusion of 100 c.c. of citrated blood was then given, and the hemoglobin rose immediately to 80 per cent but slowly came down to 43 per cent on the twenty-sixth day. A second transfusion of 100 c.c. of citrated blood caused immediate rise of the hemoglobin to 89 per cent, where it remained until discharge. Samples of blood from the baby and the parents were sent to Dr. Wiener, who reported the mother to be Rh negative and the father and the child Rh positive. No diagnostic serum was available at the time and the Rh factor of the blood transfused was not determined.

I may briefly cite three illustrative cases in which a determination of the Rh factor was of utmost importance.

Mrs. N. gave birth to a hydrops and lost a considerable amount of blood. This was in the days when the importance of the Rh factor was not universally appreciated and no facilities were available for obtaining Rh negative donors. The clinician immediately ordered a transfusion which was done with the result the patient developed an anuria and elevated blood urea nitrogen.

In 1938, Miss X. was a patient at the age of eighteen with a diagnosis of encephalitis. She received four blood transfusions during her confinement in the hospital. She had since been married. Her first child died of erythroblastosis. She was found to be Rh negative.

Mrs. P. was admitted because of bleeding peptic ulcer. Her hemoglobin was 45 per cent. The usual blood groupings and cross-matchings were done, and the patient was receiving a transfusion of compatible blood. She developed a severe reaction before 100 c.c. of the blood had been administered. Regroupings and recross-matchings proved no error on the part of the laboratory. Then, Rh determination was ordered. This showed the answer. The patient was Rh negative.

In conclusion, I wish to recommend the following procedure:

Routine determination of the Rh factor in all hospital admissions may not be practical. However, in the light of our present knowledge and experience with the Rh factor and the intragroup transfusion reaction, it is recommended that the following procedure be followed, in order to prevent the transfusion reactions in which the Rh factor is found to play a decisive role.

1. All patients who come under the following category should have their Rh factor determined along with the usual blood grouping and cross matching, before the transfusion:

(a) All women who give a history of having been pregnant.

(b) All women who give a history of having had one or more miscarriages or abortions, or having had a baby or babies who had jaundice or died soon after birth.

(c) All patients who give a history of having reecived one or more transfusions, regardless of whether they had any reaction or not.

2. Every gynecological and obstetrical patient should have her Rh factor determined. If the factor be negative, it would be desirable to have her husband's and children's bloods tested for the Rh factor.

Clinical Discussion

E. M. Kasper, M.D.

Erythroblastosis fetalis is a term which personally I do not like. Hemolytic anemia of the newborn is preferable. My opinion is that hydrops fetalis is the most severe form, and then in decreasing grades come icterus gravis and congenital anemia of the newborn. I think they are all one and the same disease. Luckily we do not run into them very often, probably in only about 0.2 of one per cent of all births. This figure needs an explanation because, after all, 15 per cent of the mothers are Rh negative, and we wonder why we do not run into it more frequently. Individual variations in the permeability of the placenta may explain some of them. Also, there must be more than one pregnancy, as a rule, to produce an erythroblastosis. The modern tendency to restrict the number of children in the family is therefore a large factor in keeping down the number of erythroblastotic babies. Another explanation is that very often the condition escapes recognition. Some of these erythroblastotic babies are born with a mild anemia which, in the past, has not been attributed to the Rh factor. We also know that many husbands are heterozygous; that is, they have both the Rh positive and the Rh negative genes. In that event, some of the babies may be normal. It is interesting to calculate on the frequency of such marriages. Probably not over 5.5 per cent of all marriages are between men who are homozygous and women who are Rh negative, so the frequency would be cut down considerably just by that alone. Among American negroes and American-born Chinese, the incidence of the positive Rh factor is much higher. In the Chinese, the incidence of the Rh negative is said to be less than 1 per cent against 15 per cent among the white population. Many more male children are affected than female children. Another interesting point is in the recent work that some men are doing on feeble-mindedness. It was shown definitely from their study that there is some relationship between feeble-mindedness and this condition.

With hydrops fetalis, we have an obstetrical problem in which we often treat the mother for toxemia without really knowing the cause of it. There are a number of cases of hydramnios. The deliveries are very difficult, and the percentage of breech is increased, as are the other forms of abnormal presentation. Practically all babies die. With icterus gravis, on the other hand, we usually do not have very much of an obstetrical problem, because here the baby is not usually large and does not show any abnormality, except that it may be born jaundiced. The mortality among these babies was up around 75 per cent. It has dropped down now to about 15 per cent with the proper treatment. With congenital anemias of the newborn we do not have very much of an increase in obstetrical difficulty.

Regarding treatment, it is not clear just what we can do. We can say that the transfusions of Rh negative women with Rh negative blood should always be done. We have to be sure, however, that we do not use Rh negative donors who have been previously transfused with Rh positive blood, because they may transfer the anti-Rh agglutinins to the recipient. The transfusion of an erythroblastotic infant with Rh negative blood of the same group should also be done, if possible. Some men, on the other hand, claim that it is better to use Rh positive blood even though that blood is rapidly destroyed in the baby's circulation. The point raised by these men is that the Rh positive blood will neutralize some of the anti-Rh agglutinins in the fetal blood stream. Some men advocate using Rh negative and Rh positive blood alternately. We should never use the mother's blood, unless the cells are washed in saline before administration. The importance in treatment is to treat early and not to wait until the advanced symptoms are developed. The hospital should keep a list of Rh negative donors, and where we suspect the baby is going to be born

---

Dr. Kasper's paper has been somewhat shortened and the report of his cases is entirely omitted.

affected, we should have a donor ready. There has also been considerable discussion as to whether we should do cesarean sections on these mothers. I am not particularly sold on this idea, except in selected cases. The important thing in these cases is to watch the titer after the seventh month. Often we find that the titer does not rise at all; sometimes the titer will be rather high and all of a sudden it will drop; sometimes the titer will suddenly rise. There is no consistency. The only thing is to remember that when the titer does start rising, or if the titer does start falling, we have an indication of some trouble. When the titer falls, it means that the anti-Rh agglutinins are taken out of the mother's blood into the fetal blood, and these babies are apt to be hydrops.

The Rh tests are much more important during pregnancy than the Wassermann. I have found that, in over a thousand women, I did not find a single case of positive Wassermann where I had not suspected it before, or the mother knew it. With the Rh test, the percentage of the negative is much higher. I think the secret lies in trying to find some foreign material that is going to wipe out the anti-Rh agglutinins, but as yet we have not been able to find such a substance. It is important to tell Rh negative mothers with Rh positive husbands, that it is advisable not to have children too closely together, the consensus is about once every five years. That is in order to let the titer fall down in the mother's blood stream after pregnancy and to return to normal. The Rh negative mother should not nurse her Rh positive child. This condition is very interesting to the obstetrician, and as yet we do not have the answer. We hope that sometime or another we can show these mothers who are Rh negative and have Rh positive husbands that they can have a normal, living baby. The answer is not here today.

Differential Diagnoses—Kernicterus

Robert Rosenthal, M.D.

So much has been said about erythroblastosis that I think it is time we say something about the cases that are not. Therefore, I want to say something about the differential diagnosis. There are various conditions that look very much like erythroblastosis. First, common icterus neonatorum, simple physiological icterus, at times is very pronounced, particularly in the premature infant. It can be very pronounced and can appear very early, during the first day, and that is usually a characteristic of erythroblastosis. The premature infant, too, with icterus neonatorum may have more normoblasts than we usually find; i.e., over 5,000 per cu. mm. but if the number is considerably higher, the case should be viewed with suspicion. Usually we find also that when the number of erythroblasts have reached its maximum, it should return to normal without any particular treatment within a day or two, and there is usually no anemia in the first few days. Secondly, congenital lues can very easily simulate erythroblastosis fetalis. There may be icterus, splenomegoly, hepatomegaly, anemia, and a large number of circulating erythroblasts. Of course, the mother's Wassermann is extremely important because in the infant only a positive Wassermann can be depended upon. Dr. Ikeda mentioned something about the x-ray picture. That is very important because the x-ray pictures in erythroblastosis fetalis are just beginning to be studied and the changes are sometimes somewhat similar to those of congenital lues. Then, severe infections and particularly sepsis may produce a very severe icterus, enlarged liver, enlarged spleen, and often an increase of erythroblasts that appears several days after birth and usually appears after the onset of infection. Very often the focus of infection can be discovered. The septic temperature and the positive blood cultures help to clear up the diagnosis. Now, in the cases of congenital atresia of the bile duct, we have a very pronounced icterus, but usually there is no particular increase of the erythroblasts, though this can occasionally happen. The acholic stools are, of course, most important in differentiating this condition. Icterus usually appears a little later in the newborn period, but it may come at once. Then there is the large group of intracranial hemorrhage. That may at times simulate erythroblastosis fetalis, but the blood picture, the liver, and the spleen usually remain normal. Another condition, hemorrhagic disease of the newborn, may occur at about the same time as erythroblastosis fetalis. It may have a full-grown picture on the second or third day of life, and hemorrhages may occur in erythroblastosis fetalis, though here the hemorrhages are usually of a terminal nature. It should be kept in mind, too, that erythroblastosis fetalis also shows a diminished prothrombin. Congenital heart disease can be confused with erythroblastosis. Edema may be present, and the liver and the spleen may be large. The erythroblasts may reach as much as 25,000 per cu. mm. on the first day. The differential diagnosis may be particularly difficult if there is an early physiological icterus. I think that during the past year, it has been shown that idiopathic cardiac enlargement is found fairly often in erythroblastosis; but in congenital heart disease, there is usually no family history, no hemolysis and no anemia. On the other hand, there is an increased hemoglobin and increased red blood count. Of course, the determination of the Rh factors of the parents of the patient are extremely important. I do not want to say any more about some types of congenital icterus that are very rare and are not of erythroblastotic origin.

I would like to comment on one of the symptoms of erythroblastosis fetalis, the so-called kernicterus. We have adopted the German name. We usually call it icterus of the basal ganglia. This condition was first described seventy-five years ago, but did not receive its name until 1903. It has been shown that there are certain portions of the brain, particularly the basal ganglia, the cornu ammonis, even certain parts of the spinal cord, occasionally become stained with bile. It is a very rare condition. In one very early series of 120 cases of severe icterus gravis only six cases show kernicterus. The interesting point is that kernicterus appears only in the newborn period, never in the adult. It never appears in an obstructive type of jaundice. It apparently appears only in cases of erythroblastosis fetalis. It is not a disease in itself. It is just one of the lesions found in these cases of severe jaundice. The cause has not been definitely determined but the one thing that we have learned is that apparently only abnormal cells, the cells that have become damaged, degenerated, or necrotic will be stained with the bile. Now, it seems that the damage of these cells has to take place before the staining takes place. The anoxemia comes in here. Children fairly often are born asphyxiated and these stained cells, these stained basal ganglia, are very sensitive to anoxemia. They are damaged very early. It was shown, too, about fifteen years ago, that these particular areas like the cornu ammonis have a particularly poor blood supply and therefore are particularly easily damaged by anoxemia. At present, the best hypothesis is that these ganglia are very susceptible to damage by anoxemia, and the staining with bile is secondary, but this hypothesis does not explain the almost 100 per cent association of kernicterus in erythroblastosis fetalis and its consistent absence in other conditions. Thus, a new hypothesis has come up claiming that apparently the anti-Rh agglutinins act with a specific toxin on those cells, the antigen sensitizes them, and then they become bile stained. The histologic picture is the demyelinization and degeneration of the nerve cells, and we designate its characters not on its pathologic picture but on the clinical picture. We may have early symptoms of lethargy, convulsions, twitchings, but very often the symptoms are not found until late. It may take weeks or months before the symptoms appear. The late symptoms are various kinds of apathy, choreiform movements, delayed static functions. Practically every case shows mental retardation. There may be varied degrees of spasticity. It is one of the conditions that we have not paid very much attention to, but we will have to consider it in any case of icterus gravis combined with erythroblastosis. There is one case on record, where a child died at the age of three years, a child who had had erythroblastosis and icterus gravis and was extremely icteric and showed the typical symptoms of kernicterus, but when he was autopsied, degeneration of the various areas was found, but no staining was found. These are to be found exclusively in cases of erythroblastosis.

General Discussion

Dr. N. J. Lilleberg: Originally, the Rh factor was of interest only to obstetricians and pediatricians, but now it becomes apparent that any Rh negative woman who is given blood either intravenously or intramuscularly is liable to become sensitized before her obstetrical careers begin. Levine has shown in a large series of cases that Rh negative women who had, in their first pregnancies, erythroblastotic babies, had been sensitized either in childhood or at birth. In one case, a mother received a transfusion fourteen years previously; her first baby was an erythroblastotic baby. But, for all practical purposes, we perhaps have to assume that once these mothers become iso-immunized to the Rh positive factor they remain iso-immunized the rest of their lives. As yet, it has to be proved that a number of years of lapse between babies will change that factor any. The antibody titer decreases after a few years or even after months, but the reticulo-endothelial system still retains the power to rapidly develop antibodies which again will develop erythroblastotic babies. Levine has shown that 0.13 c.c., between 0.1 and 0.2 c.c., of blood will sensitize a mother and produce erythroblastotic babies. Therefore, if we are giving transfusions to Rh negative infants or children, we have to be very careful and give them Rh negative blood. In New York, during the plasma drive, somebody conceived the bright idea of suspending the red cells. Why throw away the red cells that we have been saving from the plasma? Suspend these red cells and give them to the charity hospitals and use them for transfusion purposes. Eighteen women who received these red cells aid were followed subsequently, gave birth to erythroblastotic babies in their first pregnancy. At the present time, we can only say that any mother who has one erythroblastotic baby should perhaps not become pregnant again.

Dr. Woodard Colby: There apparently is still argument as to when to transfuse. When anemia is present at the time the infant comes under observation, then there is no question that prompt transfusion is advisable and this must be repeated at regular intervals until the blood destruction stops. Infants in a critical condition, or with bleeding tendencies, even in the absence of anemia, must be given small, frequent transfusions. Rh positive, Rh negative, and bank bloods have been used with good immediate results in raising hemoglobin and improving the child's clinical condition. But, the Rh negative blood transfusions caused a better sustained rise in hemoglobin, fewer reactions, and lower mortality. If the baby is not anemic, then the use of transfusion may be questioned. The hemoglobin and red counts must be done once or twice a day for about the first ten days and then as indicated. Vitamin K may be given to the blood donors and to the infant but the lack of a good response is probably due to a liver damage. In the Swendson case that Dr. Ikeda has on the board, that child was a very icteric child and the icterus and nucleated red cells lasted from three to four months. The mother told me today that for the first three years the child's teeth were very dark and bluish-black. Now, at the age of six, the teeth are nice and white and clean. I see that Dr. Ikeda's figures run almost equal—males to females. The general figure is about three males to one female, and in the fatal cases is about five or six males to one female.

Dr. L. W. Barry: Until we can desensitize these Rh negative mothers, until we can immunize them against the iso-agglutinins or anti-Rh bodies, we are up against it. I do not know how we can do it. I do not think cesarean section or watching the titer is any solution of the problem. When you do not know what else to do, you transfuse the woman. The patient gets transfused again and again and again. These women are going to be habitual aborters and are going to give birth to erythroblastotic fetuses. We may work on the problem and get something new, so that we can desensitize these women, but so far, I think that after a woman has had two babies she has had just about enough if she is Rh negative. I had one patient who had seven miscarriages, and I told her she could have a cesarean if she wanted it. She did not want it, and she delivered a macerated fetus. In another case, we were watching the titer, and we thought of doing a cesarean. She delivered a perfectly normal baby before anyone could get there.

Dr. X: In a case where a woman had an Rh negative factor and had had a couple of dead babies, would you sterilize her?

Dr. Roger S. Countryman: I did that. One of the dispensary patients had a history of five pregnancies without a living child; three were born living. She had nearly died of anuria with the fourth one following a transfusion, and we did not know about the Rh factor at that time. She was anuric for five days. When she became pregnant the fifth time, with the consent of the patient and her husband, I did a hysterotomy and sterilized her. I think it is justified in such a case.

Dr. Edward Schons: In regard to the x-ray appearance, I think rather than a thickening of the cortex, what you have is a widening of the bone due to an increase in the medulla and a thinning of the cortex. You see that in the skull and in all the long bones. I do not believe that it simulates syphilis.

Dr. W. Ray Shannon: As regards decision whether Rh factor positive or Rh negative blood shall be insisted upon for transfusion of newborn infants showing erythroblastosis, I should like to raise a question. Presumably, an infant suffering from erythroblastosis, the moment his umbilical circulation is interrupted, is a little bundle of antibodies against Rh positive blood cells. Theoretically, at least, these must be neutralized before the infant can hope to carry on under his own power so far as red blood cells are concerned. They should be capable of neutralization by any Rh positive blood cells. It seems, on the surface, that the sooner that established mass of antibodies are neutralized the better for the infant. That would have to be fact unless the products of cell destruction became an important element as regards the safety of the infant. The only argument that those who would insist upon Rh negative blood transfusion can rely is the assurance that sudden release of the products of red cell destruction does result in greater damage to the infant economy than would a situation in which an artificial transport for oxygen were provided while a gradual destruction of the infant's own oxygen transport system went on. It has never been defined to me exactly where, in the process of red-cell development in the infant, the antibodies against his blood cells begin to take hold. If it should so happen that they act at any stage earlier than complete maturity then it should be evident that the quicker they were neutralized by such an antidote, say, as adult cells supplied by transfusion, the better. The answer to this question lies, in my mind, in the future.

Dr. Rosenthal mentioned kernicterus in connection with the form of jaundice we are discussing. He spoke of it as a postmortem finding calling attention to the fact the jaundiced condition of the brain cells did not occur except in brain cells previously damaged. I agree heartily with his implications that it is a postmortem diagnosis and not subject to clinical consideration.

Dr. Ikeda: During the first few days of the baby's life, it is assumed that the degree of hemolysis of its blood is in proportion to the amount of the anti-Rh agglutinins in its circulation. The more anemic or jaundiced the baby, the higher the titer of the anti-Rh agglutinins in its blood. Under such a circumstance, it would seem of more practical and immediate importance for the baby to have a sufficient amount of Rh negative blood in circulation just to maintain its oxygen-carrying function to combat anoxemia, which is likely to be the direct cause of death. Rh positive blood, which is known to be destroyed in four or five days, is given to neutralize the anti-Rh agglutinins, but what about the supply of oxygen which is most needed by the baby? Furthermore, a sudden, massive destruction of incompatible blood within the baby's circulation may cause a shock which may have a disastrous effect on the baby. I would say that if at all possible, the first and immediate transfusion should be done with Rh negative blood. I am particularly glad that Dr. Rosenthal has given us a very comprehensive summary on kernicterus, which has been neglected by many of us who have become absorbed in the hematologic and immunologic aspects of the Rh fac-

(Continued on Page 284)

THE TREATMENT OF ACUTE ARTERIAL OCCLUSION OF THE EXTREMITIES WITH SPECIAL REFERENCE TO ANTICOAGULANT THERAPY

NELSON W. BARKER, M.D., EDGAR A. HINES, JR., M.D., and WALTER F. KVALE, M.D.

Rochester, Minnesota

ACUTE arterial occlusion of the femoral or brachial arteries by embolism or thrombosis is a serious medical emergency. Delayed, inadequate or wrong treatment for this condition often results in extensive gangrene.

In cases in which acute arterial occlusion develops a serious underlying cardiac or arterial disease usually is present and therefore the occlusion in the extremity may be only a forerunner of even more serious arterial occlusion elsewhere; for example, in the arteries of the brain, mesentery, lungs or heart. Many patients who have acute arterial occlusion are poor surgical risks because of the cardiac or vascular disease. If gangrene develops and amputation is necessary the patient may succumb in the immediate postoperative period.

Acute arterial occlusion of the extremities may be due to embolism or thrombosis. Arterial embolism occurs as the result of detachment of a thrombus in a fibrillating auricle (which is the most common cause), from a detachment of a mural thrombus which has developed at the site of a large recent myocardial infarct or from a detachment of a portion of a vegetation which has occurred in acute or subacute bacterial endocarditis. Two rare causes of arterial embolism are the detachment of a thrombus in a systemic vein and passage of the embolus from the right side of the heart to the left side through a patent foramen ovale, and the detachment of a thrombus in the aorta or a large artery which becomes impacted at a more distal and narrower point in the arterial tree.

Acute arterial thrombosis *in situ* develops most commonly as the result of arteriosclerosis obliterans at a point where extensive atheromatous change has occurred. It occurs less commonly as a result of thrombo-angiitis obliterans. In a third condition, simple arterial thrombosis, the thrombus develops with minimal or no apparent disease in the arterial wall. Simple arterial thrombosis may occur in blood dyscrasias, particularly polycythemia vera, as a complication of serious infectious diseases even in young adults, during congestive heart failure or as a postoperative complication. Rarely it occurs in young adults without known cause or antecedent disease.

The clinical manifestations of acute arterial occlusion are quite characteristic. Severe pain in the affected extremity usually is present and frequently, but not always, the pain develops quite suddenly. In a few cases the condition develops gradually in a few hours. Pain may be present in the entire leg or arm but usually it is most severe in the most distal portion. The extremity is pale and cold and the superficial veins are collapsed. Some degree of hypesthesia is usually present and anesthesia of the glove or stocking type may occur. There may be partial or complete loss of motor function. Below the point of occlusion arterial pulsations are absent. The diagnosis is based on these clinical manifestations.

Some important points in the physiology of acute arterial occlusion should be considered because they influence treatment. Ten years ago McKechnie and Allen[2] emphasized the fact that acute occlusion of an artery is almost always followed immediately by a severe arterial spasm which affects not only the main arterial trunks below the occlusion but also many of the collateral anastomosing arteries. This spasm is a major contributing factor to the severe acute ischemia of the limb. The spasm may endure for many hours before relaxation occurs spontaneously and, when the spasm finally does subside, severe damage may have occurred in the endothelium of the arteries distal to the occlusion as the result of prolonged ischemia. Secondary arterial thrombosis develops in these distal arteries when the spasm relaxes and, in such cases, extensive gangrene of the limb almost invariably follows. During the period of arterial spasm there may be considerable ischemia of nerve trunks which are very sensitive to deprivation of arterial blood supply so that, even though the circulation may

---

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

ultimately be restored, ischemic neuritis will be a persistent residuum. Another factor which is important in treatment is that thrombosis may continue to develop at the site from which the embolus was detached and be a potential source for more emboli. In the case of occlusion by thrombosis *in situ* the thrombosis may progress in a proximal direction, occluding more and more of the collateral anastomosing arteries, and therefore may result in more serious and irreversible ischemia owing to organic arterial occlusion which is entirely separate from the secondary arterial spasm. For these reasons, two of the cardinal principles of treatment are: (1) relax the arterial spasm as soon as possible and (2) institute as rapidly as possible measures to prevent further thrombosis.

TABLE I. ACUTE ARTERIAL EMBOLISM OF EXTREMITIES

Anticoagulant Therapy

Case	Probable source of embolus	Location of embolus	Duration of therapy, days	Result
1	Fibrillating auricle (rheumatic heart disease)	Right popliteal	14	Recovery of limb
2	Fibrillating auricle (rheumatic heart disease)	Right femoral	54	Recovery of limb
3	Fibrillating auricle (rheumatic heart disease)	Left femoral; both brachials	27	Recovery of all limbs
4	Fibrillating auricle (rheumatic heart disease)	Right brachial	10	Recovery of limb
5	Fibrillating auricle (rheumatic heart disease)	Left brachial	15	Recovery of limb
6	Mural intracardiac thrombosis (myocardial infarction)	Left femoral	11	Recovery of limb; death from cardiac failure

TABLE II. ACUTE ARTERIAL THROMBOSIS OF EXTREMITIES

Anticoagulant Therapy

Case	Arterial disease	Location of thrombus	Duration of therapy, days	Result
1	Thrombo-angiitis obliterans	Right femoral	37	Recovery of limb
2	Thrombo-angiitis obliterans	Right femoral	22	Recovery of limb
3	Arteriosclerosis obliterans	Left femoral	10	Recovery of limb
4	Arteriosclerosis obliterans; diabetes	Right femoral	14	Recovery of limb
5	Arteriosclerosis obliterans; diabetes	Right femoral	9	Gangrene; amputation
6	Thrombosis, postoperative; transurethral resection for carcinoma of prostate	Left brachial	7	Recovery of limb
7	Thrombosis, postoperative; exploration for carcinoma of pancreas	Left femoral	16	Recovery of limb; minor bleeding mouth and rectum
8	Thrombosis, postoperative; radical mastectomy for carcinoma of breast	Right femoral	7	Gangrene; amputation
9	Thrombosis, postoperative; exploration for carcinoma of pancreas	Left femoral	4	Gangrene; amputation; death 7 days later

In their previous report, McKechnie and Allen also emphasized the seriousness of acute arterial occlusion by indicating the results in fifty-seven cases of arterial embolism and sixty cases of acute arterial thrombosis. The patients were treated in various ways, some of which, in view of more recent developments, were probably inadequate, and they did not receive anticoagulant therapy. In slightly more than 45 per cent of the cases of arterial embolism and in slightly more than 50 per cent of the cases of acute arterial thrombosis, gangrene developed. Of the forty-two deaths (36 per cent of 117 cases) in the period immediately following the acute occlusion, four occurred soon after the occlusion without gangrene; twelve occurred following amputation, and in twenty-six cases, gangrene was present but death occurred before amputation of the affected extremity had been performed.

At the present time we feel that the following are important points in the medical treatment of acute arterial occlusion of the extremities:

1. Make the diagnosis early.
2. Start treatment immediately.
3. Do not elevate the extremity.
4. Do not apply heat locally in any form.
5. Use the Sanders oscillating bed in the maximal low foot and minimal low head position. If such a bed is not available, elevate the head of the bed twelve to fifteen inches.
6. Keep the room temperature between 80° to 85° F.
7. Give ½ grain (0.032 gm.) of papaverine hydrochloride intravenously.
8. Give 1½ fluid ounces (45 c.c.) of whisky every four hours.
9. Give heparin and dicumarol.

Attention is called to the specific point that the extremity should not be elevated. When acute venous occlusion develops, elevation of the extremity is advisable, but obviously elevation is never advisable in the presence of acute arterial occlusion because the markedly impaired blood flow through the arteries then will have to overcome gravity also and elevation may render a partially ischemic foot or hand more ischemic than before elevation.

Inasmuch as the extremity is cold after acute arterial occlusion, a rather widespread procedure among patients, and even physicians, is application of some sort of heat locally to the skin. This should never be done. The use of hot water bottles, electric pads, hot packs, bakers or heating lamps is absolutely contra-indicated, because after acute arterial occlusion the skin is very ischemic and burns will develop if a minimal amount of local heat is applied directly to the skin. Furthermore there may be hypesthesia or anesthesia of the skin and the patient may not realize that the skin is being burned. In many instances, gangrene has developed entirely as the result of such burns.

We feel that the use of the Sanders oscillating bed is superior to intermittent suction and pressure and intermittent venous occlusion, for the treatment of acute arterial occlusion of the lower extremity.

The high room temperature, papaverine and whisky are used to produce vasodilatation and are usually successful. However, if papaverine is not effective after the first dose, subsequent doses are rarely effective, and it is unnecessary to repeat the injection.

The plan for anticoagulant therapy is as follows[1]: Fifty milligrams of heparin should be given intravenously every four hours, 300 mg. of dicumarol should be given by mouth immediately and 200 mg. should be given on each succeeding day when the prothrombin is greater than 20 per cent of normal. This plan necessitates daily prothrombin time tests. The blood should be withdrawn for the prothrombin time test each day three hours after the intravenous injection of heparin. If, on the first day, the prothrombin time falls below 20 per cent of normal the administration of heparin may be discontinued. If this plan of medical treatment is instituted early, that is within a few hours after the acute occlusion has occurred, it is usually effective both in terminating the arterial spasm and in preventing further thrombosis. If the arterial spasm does not disappear within twelve hours after the treatment has been started, the sympathetic ganglia supplying the affected extremity should be anesthetized with a local anesthetic agent; and if this also fails to release the arterial spasm and the limb has shown no signs of improvement in the arterial circulation, embolectomy or thrombectomy should be seriously considered. However, embolectomy is rarely necessary and thrombectomy is not often successful.

We have treated acute arterial embolism in six cases and acute arterial thrombosis in nine cases by this plan of treatment. The results are summarized in Tables I and II. In these tables "recovery of the limb" means that gangrene did not develop, that pain was relieved and function was restored. It does not mean that the circulation to the limb was restored entirely to normal because usually there was persistent impairment or absence of pulsations in the affected extremity and some mild to moderate persistent arterial insufficiency. It will be noted that function of the limb was restored in all cases of embolism and in six of the nine cases of acute thrombosis. There was one death in each group. Bleeding as the result of anticoagulant therapy occurred in only one case and the bleeding was minimal.

CLINICAL-PATHOLOGICAL CONFERENCE

DIAGNOSTIC CASE REPORT

ARTHUR H. WELLS, M.D., and F. H. DICKSON, M.D.
Duluth, Minnesota

Dr. A. H. Wells: Case 3245 has proved to be one of our most interesting pathologic studies of the year. The clinical history has been summarized from the charts of three Duluth hospitals, yet there may be important missing symptoms.

Dr. H. S. Marshall: This sixty-five-year-old retired storekeeper was admitted to the hospital November 19, 1945, two days before his death, complaining of severe nasal bleeding of two days' duration. He was quite unco-operative in regard to relating the nature of his illness. However, he did tell the nurse that he felt very weak from the loss of blood.

His past history included a ruptured, gangrenous, gallbladder with local abscess formation, in 1941. A cholecystectomy and drainage of an "orange"-sized abscess in the gall bladder area was performed at the Webber hospital. A duodenal fistula developed postoperatively, only to close spontaneously within one month. One year later a "grapefruit"-sized hernia protruding through the operative scar was repaired. In April of 1943 he sustained a fractured nose and a laceration over the right eye as the result of a fist fight. There was no loss of consciousness at the time. The fractured nose and laceration were repaired by his physician who later noted that—although the patient had been a rather obese, affable, personality with a tendency to heavy drinking—he became a distinctly disagreeable, good-for-nothing, chronic alcoholic who, in rapid succession, mortgaged his store and lost it and mortgaged his home and lost it, using the money so obtained to purchase, on the average, over one and a half quarts of whiskey a day. During this period of approximately two and a half years, he had had several attacks of what was considered intestinal obstruction, generally lasting two or three days. On three occasions he was admitted to a hospital where, following the use of Wangensteen's decompression tube therapy, he showed rapid improvement. The history relating to one of these admissions to St. Mary's Hospital reveals that he had had eight to nine emeses every day for six days preceding admission. There apparently had been no bowel movements during this period of vomiting. Headaches were not mentioned. He claimed to have refrained from using alcohol for three weeks. It was also learned that after his alcoholic bouts his vomiting and abdominal "gas" pains would become worse. He had had rheumatic fever twenty-five years previously.

His physical examination was essentially negative. The blood pressure was 130/80 and temperature 100° F. The abdomen was soft, non-tender, and had no palpable masses. His white blood cell count was 10,400 with 75 per cent neutrophiles and 21 per cent lymphocytes. The red blood cell count was 4,300,000 and the hemoglobin 12.2 grams. The blood Kline test was negative. On the second hospital day he was greatly improved with gastric decompression therapy. His obstruction was relieved and he left the hospital on the third day.

On admission to this hospital, he was somewhat obese and his muscles were flabby. His white blood cell count was 13,350; red blood cell count 4,100,000; and hemoglobin 13.5 grams. There were 88 per cent neutrophiles. Urine examination was essentially normal. His temperature was 99° F., and respirations 18 per minute. The abdomen was relaxed and did not contain a palpable mass. There was marked pulmonary emphysema. Heart tones were distant and free from murmurs and irregularities in rhythm. The pulse was 80 per minute. The blood pressure on several occasions was 150/100. During his last two days there was no further nasal bleeding, and he rested quietly. There was no apparent suffering except for some nausea and undescribed pain in his abdomen. He vomited about 150 c.c. of light colored fluid about six hours before his death.

Dr. A. H. Wells: The case is now open for diagnoses.

Physicians: Coronary thrombosis with myocardial infarction; carcinomatosis of peritoneal surfaces; tuberculous peritonitis; high intestinal obstruction, due to adhesions; brain tumor; chronic subdural hematoma.

Dr. A. H. Wells: Dr. Tuohy's diagnosis is correct. Would you tell us what led you to the proper diagnosis?

Dr. E. L. Tuohy: A serious change in character or mental status following an injury to the head, associated with recurrent evidences of increased intracranial pressure such as bouts of vomiting, should always make one consider subdural hematoma.

Necropsy

The necropsy revealed a remarkable combination of a cystic degeneration of the dura with a "subdural hygroma" on the left side and a chronic intradural hemorrhagic cyst, "chronic subdural hematoma," on the right side. The hemorrhagic cyst had caused a severe compression of the entire length of the right cerebral hem-

---

From the Department of Pathology of St. Luke's Hospital, Duluth, Minnesota, Arthur H. Wells, Pathologist.

isphere so that its surface over a large area was concave instead of convex as seen in this kodachrome slide. The lesion extended from the anterior most frontal area to the posterior most occiput and involved about one-half of the distance between the sagittal sinus and the base of the skull along this entire distance. It measured from 1 to 2.5 cms. in thickness and was composed of a fairly thick-walled cyst demonstrated in this kodachrome picture (Fig. 1). The cyst was filled with a xanthochromic watery fluid with scattered small dark red blood clots (x). The latter totalled about 20 c.c. Many of these clots appeared to be of very recent origin. The thick cyst walls are incorporated in the split layers of the meningeal half of the dura. The meningeal layer of the dura has completely separated from the endosteal layer under the hemorrhagic cyst. (The meningeal and endosteal layers represent the two embryonic sources of the dura). Because of this separation of the two layers of the pachymeninx one may easily break through the meningeal layer of the dura at the cyst margin (y) and lift up the thick-walled cyst, leaving the endosteal layer (z) beneath, attached to the skull bone and having every gross appearance of normal intact dura.

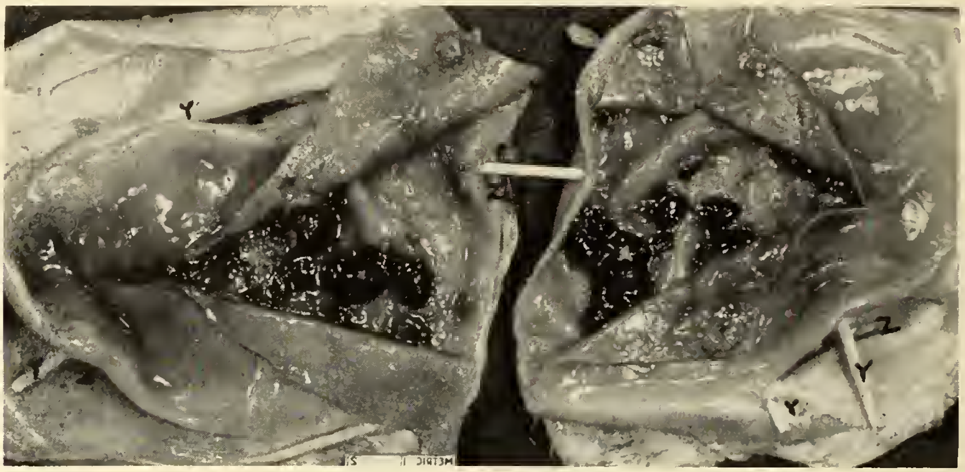

Fig. 1.—Intradural hematoma with opened cyst wall exposing recent blood clots (x), margins (y) are separated to expose endosteal dura (z).

Multiple histologic sections taken from the margins of the hemorrhagic cyst (Fig. 2) all reveal the location of the cyst within the meningeal layer of the dura (x). The endosteal layer (y) is completely uninvolved. Active fibroblastic organization of recurrent hemorrhages is most evident in this old cyst at its margin (z). It is in this new organizing connective tissue that one frequently finds huge congested and recently ruptured capillaries (Fig. 3), the obvious source of the recurrent hemorrhages within the old cyst wall.

In the superior frontal region of the left dura was a large flat cystic space filled with clear, watery fluid, measuring 6 cm. in diameter and about 5 mm. in depth. The fluid could be squeezed readily to other parts of the dura in which the layers appeared grossly intact. There was a mottling of brownish-yellow of old blood pigmeint and bright red of recent hemorrhages throughout the left frontoparietal region of the dura.

Many histologic sections taken from this entire area of the dura reveal an extensive cystic degenerative change primarily located between the inner third and the outer two-thirds (Fig. 4-x) of the meningeal layer (y) of the dura. The endosteal layer (z) has no significant degeneration. The meningeal membrane degeneration is evidenced first by fading and disappearance of fibroblasts, later by fading and disappearance of the collagenous fibrils and, finally, by the formation of cystic spaces (Fig. 5-x). These are at first microscopic in size and later grossly visible cysts. There is, in addition to this, the occurrence of small flare-like hemorrhages (y) at the margins of the normally present giant capillaries in the meningeal portion of the dura. Occasionally, a few red blood cells from these tiny hemorrhages have leaked into the cystic spaces. These giant capillaries and minute hemorrhages are seen in nearly every section taken from the frontoparietal regions of both sides of the dura. There are also many iron pigment laden phagocytes (z) —the remnants of previous hemorrhages. There is practically no inflammatory cell infiltration except for occasional lymphocytes in the immediate vicinity of the larger hemorrhages. The endosteal dura has no significant changes excepting for rare isolated pigment-laden phagocytes. A few pigment-laden phagocytes are also present in the arachnoid space in the sections from the cerebral cortex immediately underlying the hematoma. There are no significant histologic changes in the nerve cells, using routine hematoxylin and eosin stains.

Incidental necropsy findings included a grade II cirrhosis of the liver and mild toxic changes in the myocardium, liver, spleen, and kidneys. There were adhesions between the duodenum and bed of the gall bladder with some dilatation of the lumen of the duodenum but no evidence whatever of obstruction of any part of the small or large intestines. There were no diverticula, tu-

mor masses, or areas of inflammation in any part of of the gastro-intestinal tract. There was no pneumonia.

Discussion

Dr. D. W. Wheeler: Why wasn't the cirrhosis of the liver the cause of death?

Dr. A. H. Wells: The scarring of the liver was not advanced enough to be of great significance. In addition, there were only mild fatty changes in the liver cells. There was no ascites, edema, anemia, jaundice, gastro-intestinal hemorrhage, or dilatation of the portal tributaries.

Dr. W. A. Coventry: How do you know that the hematoma caused death?

Dr. A. H. Well.: The hemorrhagic cyst was quite large and had caused a great deal of compression of the right cerebral hemisphere. No other cause of death was found. The reason the patient died when he did and not a year previously may be because of recent hemorrhages into the cyst (20 c.c.) being incompatible with life, due to increased intercranial pressure.

Etiology

In spite of my limited experience with so-called chronic subdural hematoma and the present incompleteness of the literature survey of the subject, it is my opinion that the majority of neurosurgeons and pathologists have an erroneous conception of its histogenesis. At least, they rearely even consider the possibility of intradural origin.

The present most widely accepted concept of the origin of "chronic subdural hematoma"[28,33] includes: a subdural hemorrhage from injured subarachnoid veins, "bridging veins" or veins passing from the surface of the cortex to the saggital sinus; fibroblastic organization of the two surfaces of the blood clot from below into the dural surface and from its margins over the brain surface with capsule formation; central liquefaction of the blood clot and, finally, cyst formation.

In 1914 Korwitz[26] and later Hannah[16], Kaump and Love[21] and Baker[4] describe these hemorrhagic cysts as true intradural hematomas. In fact, Baker[5] feels that there is never a fibrous organization with cyst formation resulting from subdural hemorrhages, that the blood clots always absorb. To my knowledge, typical chronic hemorrhagic cysts have never been produced experimentally and are not found after craniotomy.

The many histologic sections taken from various areas of the dura of our present case and those of previous cases, reveal beyond any question, a sequence of events consisting of: (1) early idiopathic degenerative changes in the fibrous connective tissue of the meningeal layer of the dura; (2) cystic formations of varying size; (3) recurrent hemorrhages from the normal giant capillaries of the meningeal dura; (4) chronic hemorrhagic cyst formation within the meningeal dura with recurrent hemorrhages into the cyst. A somewhat similar process occurs in idiopathic medial necrosis of the aorta, resulting in dissecting aneurysm. When the facts are finally generally accepted, it is possible that all organized cystic collections of fluid and blood now generally considered to be subdural in origin are, in fact, intradural. In some cases, the basic disease process will be a cystic degenerative change of the meningeal portion of the dura, resulting in a splitting of this layer of the dura; in others there will be a splitting of the normal dura. The normally huge capillaries of the dura are subject to unusual forces not found in other capillaries of the body. These forces may be the result of changes in either the arterial or venous blood pressure of the brain or dura. They include stasis and engorgement of the capillaries due to back pressure in the veins of the dura and the frequently mentioned "dry cupping" or suction force exerted by changes in intracranial pressure. The actual hemorrhages from these capillaries may be precipitated "spontaneously" by these pressure sources or by a blow on the head, especially when the dural capillaries are engorged. Intradural hemorrhages of the newborn and of younger adults will be the result of the giant capillary ruptures with hemorrhages splitting the meningeal layer of the dura or a separation of the two embryonic layers without a preceding cystic degenerative change in the dura. These layers at times can be split normally without much difficulty. True subdural hemorrhages which do not kill will be eventually absorbed without cyst formation. Hemorrhagic diseases of the blood such as purpura hemorrhagica, scurvy, and leukemia, predispose to intradural hemorrhage. The habitual use of alcohol not only predisposes to head trauma but also either accentuates idiopathic cystic degeneration of the dura, or in some way enhances intradural capillary hemorrhages. Infectious processes of the dura of known and unknown etiology may rarely be important factors in intradural hemorrhage.

Pathologic Anatomy

Hemorrhages, in relationship to the meninges, must be classified as: (1) epidural, (2) intradural, (3) subdural, (4) subarachnoid or intrapia-arachnoid, and (5) subpial. We are concerned here with those cases in which a chronic hemorrhagic cyst formation attached to the dura is the ultimate result of the hemorrhage. These hemorrhages are nearly always located in the fronto-parietal areas over the convex portion of the cerebrum. Rarely, they are found in the occipital, subtentorial, basal, and spinal areas.[3] In a review of 204 cases described by ten authors, sixty-one, or one-third, were bilateral.[4] The gross appearance depends to some extent upon the age of the hemorrhage. Those of very recent origin will have a fresh dark red blood clot and, even if explored on the day of the injury, or within two weeks of the time of the injury, there will always be a limiting membrane holding the blood clot in the fronto-parietal area and preventing the action of gravity. Munro and Merrit[28,33] describe an inner limiting membrane of fibrin, which is later organized by fibroblasts. This is also repeatedly theorized and described by other authors as the origin of the inner membrane and, of course, touches the very heart of this controversy. There is central liquefaction of the blood clot and fibroblastic organization of the peripheral parts of the clot. New giant capillaries are formed. Finally, the wall becomes a thick, poorly cellular, hyalinized layer or laminated layers of fibroblastic tissue, which may even become calcified. Recurrent hemorrhages into the cyst cavity are common, so that the contents of the cyst may vary from a slightly xanthochromic fluid to a solid mass of blood clot in various stages of decomposition. A detailed study of the histopathology has been described in connection with our present-case study.

Clinical Manifestations

Although in any one physician's practice, cystic hematomas of the dura are rare, their potentialities are such that a thorough understanding of their clinical recognition is mandatory. In one analysis[22] of 245 cases of various authors 82 per cent were in adults and of these 87 per cent were males. There is a peak of frequency during the first year of life, and the greatest incidence occurs between the fourth and sixth decades. The history of mild trauma[5,6,7,35] preceding the onset of symptoms and signs is a generally recognized feature. Only a small percentage of the patients suffer from fractures of the skull.[6] In some patients there may be no signs or symptoms of the encapsulated hematoma.[24] However, in the majority, a thorough study of the case should lead to suspicion of the lesion, necessitating bilateral trephinement for the diagnosis. Any discussion of the subject must be divided into the manifestations evidenced in adults and infants separately. The clinical findings in adults are mainly dependent upon a rapid to extremely slow increase in intracranial pressure brought to bear primarily in the fronto-parietal regions. They are very protean and characteristically fluctuate from time to time. The condition should always be considered in patients with cranial trauma in which the symptoms do not subside after months, or even years, following the injury. In a careful study of forty-two cases of "chronic subdural hematoma" Jelsma[20] found the following frequency of clinical phenomena: mental changes 86 per cent, headaches 79 per cent, drowsiness 79 per cent, motor disturbances 70 per cent, latent period 70 per cent, coma 57 per cent, reflex changes 56 per cent, cranial nerve disturbances 47 per cent, and a lucid interval 45 per cent. Of the less frequent manifestations having a mean average of 19.7 per cent, he included in order of their frequency: choked disc, vomiting, pulse changes, increased temperature, sensory disturbances, nystagmus, retinal hemorrhage and fractured skull (4.9 per cent). Among the more frequent mental changes are failing memory, confusion, full blown psychoses, uncontrollable irrationalism, excitement, serious character depreciation, and changes in spontaneity of personality.[1,15,17] The entire gamut of psychiatric abnormalities are possible, including neurosis, mania, depression, paranoid delusions, and gross deterioration.[9] Among 3,100 consecutive autopsies of psychotic patients there were 245, or 7.9 per cent subdural hematomas.[2] Effects referable to the cranial nerves frequently include diplopia, failing vision, hemianopsia, tinnitus, and decreased hearing. A homolateral dilatation of the pupil was correct in localizing the hematoma in over 50 per cent of the cases.[1,3] This sign is explained[15] by the fact that the brain stem is shifted toward the opposite side of the tentorial opening. Later the hippocampal gyrus is forced between the brain stem and the margin of the tentorium on the same side, pressing on the third cranial nerve, causing dilatation of the pupil. The frequent finding of homolateral nerve disturbances, especially that of hemiparesis, is described as being due to either pressure of the margin of the tentorium against the brain stem on the opposite side of the lesion or else pressure of the motor cortex against the skull on the opposite side. In sixty-two cases[31] 11 per cent had visual field defects. In a review of 244 cases from the literature, 44 per cent were described as having choked discs.[23] Practically all authors agreed that in adults the diagnosis can be most easily established by bilateral trephine openings. However, many other adjuncts have been used to advantage. Encephalographic studies are recommended by some[27] and discouraged by others.[38] Generally, they are not found very useful. Psychometric tests were found of considerable value in relationship to war injuries.[1] Dural hematomas result in syndromes which can be psychiatrically distinguished from war neuroses.[1] The electro-encephalogram produces a wave pattern in cases of subdural hemorrhage which is not pathognomonic of the condition, but a valuable adjunct in its diagnosis.[36] An x-ray demonstration of the shift of the pineal gland[10] has some diagnostic value. The condition must be differentiated from brain tumor, cerebral arteriosclerosis, or thrombosis, post-encephalitic syndromes, and persistent headaches of unknown origin.[18]

Because of the frequency of subdural hematomas in infants, the great likelihood of the lesion's interfering with a rapidly growing brain, the bizarre clinical manifestations, and the ease and safety with which the lesion can be diagnosed with certainty by the use of bilateral needle puncture between cranial sutures into the dural cyst, as emphasized by Ingraham and Matson[18], it is absolutely essential for physicians caring for infants to have a thorough understanding of the condition. The generalized symptoms, such as fever, vomiting, hyper-irritability, and failure to gain weight, are frequently found alone or in addition to the more specific neurologic findings of convulsions, stupor, and paralysis. All hydrocephalics should be considered possible cases of subdural hematoma since there frequently results a separation of the cranial sutures and bulging of the fontanelles, as the result of dural hemorrhages.

Treatment

Once the diagnosis is made, all authorities agree that operation is indicated. The points of disagreement concern the size of opening through the skull, how much of the cyst membrane must be removed, and whether drains should be left in place or not. Several outstanding neuro-surgeons[20,24,25,35,39] feel that an osteoplastic flap with more or less complete removal of the hematoma and its walls is advisable. Many others[8,10,22,37] feel, for the most part, that the more simple procedure of trephine openings with irrigation and suction of the contents of the cyst and the removal of lessor amounts of the cyst wall is adequate in the majority of cases. All authorities agree that bilateral bur openings are indicated in the fronto-parietal area. The treatment of chronic dural hematoma is different for patients with fused cranial bones, as compared to that most efficacious for infants. With an experience of ninety-eight cases of subdural hematoma in infants, Ingraham and Matson[19] have advised a gradual decompression of the dural hematoma by the repeated aspiration of the contents of the cyst for a period of a week or two preceding craniotomy and complete removal of the cyst wall and contents. The gradual decompression is easily carried out with a syringe and needle and allows a period of improvement in the patient's general condition before the more extensive surgical procedure.

Summary

The case of a sixty-five-year-old chronic alcoholic with a chronic intradural hemorrhagic cyst, the immediate cause of death, on one side and a chronic intradural cyst on the other, has been described. There was an injury which may have precipitated the hemorrhage two and a half years before his death, at which time he had a serious change in personality and began experiencing repeated attacks of vomiting.

The histogenesis of the chronic hemorrhagic cyst of the dura in this case was traced to an extensive cystic degenerative disease of the dura. The question is raised whether so-called chronic subdural hematoma ever arises from true subdural hemorrhages.

A brief review of the etiology, pathologic anatomy, clinical manifestations, and treatment is included.

Necropsy Diagnosis

1. Idiopathic cystic degeneration of the dura.
2. Chronic intradural hematoma (immediate cause of death).
3. Compression of right cerebral hemisphere.
4. Intradural hygroma.
5. Cirrhosis of the liver.
6. Chronic alcoholism (from history).

FACTORS IN RURAL HEALTH IN MINNESOTA

(Continued from Page 226)

tracts at a cost which is not excessive, will be available to all of the people of Minnesota. It is anticipated that under these contracts, free choice of physician is assured. Also, it is at present anticipated that the contracts will be available to virtually any citizen of the state. Until all of the details are finally determined, it is not possible to predict the costs nor the coverage under the contract. It is expected that the plan will be a distinct step in the right direction of providing adequate, good medical care at low cost.

In conclusion, then, it seems apparent, first, that good medical care is available to all people of the state; and, secondly in the not-too-distant future, adequate, good medical care will be purchasable at a cost which any or all of the people of Minnesota can afford to pay.

NOTES ON THE HISTORY OF MEDICINE IN HOUSTON COUNTY PRIOR TO 1900

By NORA H. GUTHREY†
Mayo Clinic
Rochester, Minnesota

(Continued from February issue)

Franklin H. Whitney, born probably about 1862, was a graduate of the Hahnemann Medical College of Chicago in 1883, and it is recorded that on May 27, 1885, he received state license No. 1061 (H) to practice medicine in Minnesota. Shortly afterward he settled in La Crescent, Houston County, a village whose early hope of metropolitan growth had not materialized, and he remained there an undetermined number of years. In 1895 he served as county coroner. Information has not been available as to his career thereafter.

J. R. Wilson, a practitioner of the regular school of medicine, was certified to practice medicine in Minnesota under the Affidavit Ruling of 1887. There is record that he was in Pickwick, Winona County, in 1890, and earlier, and that in the middle nineties he was in Hokah, Houston County.

* * *

In the conduct of research in relation to early physicians in several counties of southern Minnesota it has become evident that there were many practitioners, unchronicled in official directories and reports, who drifted across the region, staying a few months or a year, leaving mention of their names in local newspapers. Some of these men were ignorant opportunists, some were sincere but incompetent, others were well trained in their day. From this mingled group some few names have appeared in these notes on physicians of Houston County, and it may well be, as was suggested earlier, that there were others of whom record has not been obtained and others still of whom no record exists. Of the able and stable practitioners, however, who maintained and advanced their profession in Houston County, it is hoped that the roster is complete.

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900*

By **NORA H. GUTHREY**†

Rochester, Minnesota

> ".....I have been able to derive much information, which if not always exact, was indicative of truth."
>
> WILLIAM W. FOLWELL,
> A History of Minnesota, 1926, Vol. 1, page xii

IN 1850 the region that soon was to become Fillmore County, Minnesota Territory, had lain for centuries in its natural beauty and productiveness, almost untouched save by time and weather. Its only inhabitants had been the wild animals that made it their home and the nomadic Indians, scarcely less wild, who roamed over it on foot or on their half-tamed ponies. In the opening decades of the nineteenth century there had crossed it, perhaps occasional white explorers and trappers.

As the fifties began to unroll, white men coming into southern Minnesota in search of homes found this region, both lovely and stern, to their liking. Of rich soil, usable limestone, abundant streams and varied woodland, it offered all they sought. Nor were they blind to the freedom of its upland prairies and the rare scenic beauty of its forested slopes and its river valleys, precipitous in the eastern portion as they neared the Mississippi River, shallower in the west; nor to the curious interest and the possible usefulness of those geologic phenomena, the "sink holes," caves and underground passages of the western stretches. Not much later the county was to be recognized as a paradise for geologists because of its ancient and varied formations and no less as a paradise for botanists because of its lush production of grasses, flowers, vines, nuts and fruits, and of trees valuable for timber, growth that even to the untutored eye was fair promise of the friendliness and bounty of the land when cultivated crops and orchards should have been introduced.

Beginning in 1851 the settlers came into what is now Fillmore County, as into all southeastern Minnesota, at first slowly, then in constantly increasing numbers, entering by the route so often mentioned: Overland to points on the eastern shore of the Mississippi River, in Illinois and Wisconsin and as far south as Kentucky and Tennessee, and thence by boat to points on the western bank.

---

*In a preceding article on the history of medicine in Houston County there was included much material relating to general history and medical history common to Houston and Fillmore Counties and other counties of southeastern Minnesota that will not be repeated here. In the present article appears new material which in turn applies not to Fillmore County alone but to Houston County and other counties of the region as well.

†A member of the editorial department, 1916-1919; 1919-1939, personal secretary and assistant to the late Dr. William James Mayo.

Many landed in Iowa; many in Houston County, Minnesota, and others came down from the little settlements of St. Paul and St. Anthony, which they had reached by northern routes. All went first to the land office at Brownsville, Houston County (later the office was moved to Chatfield, Fillmore and Olmsted Counties), and from there fanned out into the waiting land. One immigrant of these hundreds, and he must have been typical, traveled by railroad "from a town in Wisconsin to the Mississippi (LaCrosse), then took steamboat to Brownsville, then the stage to Elliota (in Fillmore County) and then on foot over the prairie" to his destination farther west.

Fillmore County, which was named for President Millard Fillmore, is the second county of the state from the Mississippi River in the tier that borders Iowa. On the east is Houston County, on the north are Winona and Olmsted Counties and on the west is Mower County. The boundaries of Fillmore County, approximately as they exist today, were established by an act of the state legislature on February 23, 1854, whereby they were much restricted from a widely comprehensive survey of a year earlier. To touch briefly on the controversies that the county experienced over the location of the county seat. First established in Winona, early in 1853, the county seat was transferred to Chatfield, obviously an illogical location, on the northern edge of the county, in December of that year; from March 2, 1855, to April 25, 1856, it was in Carimona, almost in the center of the county; on April 26, when public vote had fallen for Preston, about four miles northeast and more nearly central, Mr. John Kaercher, a substantial citizen of the county, later the founder of Clear Grit, but in 1856 in Preston, sent a man and team to Carimona for the records, which were conveyed to Preston in two coffee sacks.

The settlers entered the borders of Fillmore County on foot, with oxen, horses and in a few instances with few mules. These pioneers were of many nationalities, English, Scotch, Welsh, Irish, Bohemian, German, Dutch, Danish, Swedish and Norwegian, and whole clans as well as individual adventurers were in the movement from east to west. Many came directly to Minnesota from their native lands across the Atlantic; others were from families who had lived for a generation, or several generations, in New England or along the Atlantic seaboard; still others had pioneered in the thirties and forties from the East into Ohio, Indiana, Wisconsin, Michigan and elsewhere. Fillmore County became, and has remained, one of the most populous counties in the state; there were 13,542 inhabitants in 1860; 4,000 more in 1865; and in 1875 there were more than 28,000. From census to census since 1870 the population, preponderantly Scandinavian, has not varied more than 4,000; the peak was reached in 1895 with a population of 28,599.

Although the settlers retained many of the Indian names long established in the territory, they stamped on their new land their own names and nationalities, their hopes and homesickness, their imagination, political beliefs and religious faiths in the titles that they gave to natural formations and to civic divisions and organizations, as one may see who scans a map on which creeks, rivers, swamps, rocks and hills, townships and villages are indicated.

These people were of all occupations and professions. They promptly cleared and planted land; established local governing boards; built homes, many schools, and churches of a dozen denominations. Those from New England, especially, evincing hope and faith in the local water power, founded mills of different kinds, utilizing every stream; disappointingly soon the water power proved to be inadequate and all but a few mills and waterwheels eventually were abandoned. In some communities vestiges of the dams and wheels can still be seen. They opened manufactories of the staple articles needed by all: woolen material, furniture, brooms, barrels, boxes and shingles, wagons and sleighs. They opened stores and blacksmith shops and tin shops. They helped to promote and support a network of stage-lines that carried mail and throngs of passengers.

In Fillmore County, as in contiguous counties, to meet the needs of the many travelers there came into being wayside taverns which provided stables and "trusty ostlers" for the horses and extended almost fabulous hospitality to the public. To name only a few of these inns, famous throughout the state, which still live in memories, there were the Carimona House, in the village of Carimona, and the Stanwix in Preston, the Medary House in Chatfield. The famous Old Territorial Road was surveyed in 1855 over a trail of earlier use and passed from St. Paul through Cannon Falls, Oronoco and Rochester and, in Fillmore County, through Chatfield and southeasterly across the county into Canton Township and on to Dubuque, Iowa. Another route in the county followed the South Branch and the main stream of the Root River, passing the sites of Rushford, Carimona and Forestville, and gave access to La Crosse through Hokah on the east and to Mankato through Blue Earth on the west. In the southern part of the county and the northern part of Winnesheik and Howard Counties, Iowa, the pioneers reached Brownsville, Houston County, and La Crosse over the Norwegian Ridge Route. One branch of this road, in southeastern Fillmore County, passed through Elliota, south of the present town of Canton (founded in 1879), and, once in Houston County, turned northeast. The other branch, a few miles north, originated in the south central part of Fillmore County, passed through Lenora and Newburg and entered Houston County near Rushford. These two branches converged on Diamond Ridge and separated at Caledonia, diverting traffic respectively to Brownsville and to Hokah and La Crosse.

In Fillmore County physicians and lawyers among the settlers opened offices and hardy editors founded newspapers, which sheets were of varying fortunes. One proprietor said plaintively, "As is well known, there is a great mortality among new newspapers, the death rate exceeding even that of the human race; in fact, as many newspapers relatively die before five months of age as children before five years." But at least they disseminated information to the eager pioneers. And some of the utterances, often rhetorical, of editors give now much knowledge of conditions then, as for instance, about transportation. Among the stage-lines and mail routes through the county were those of O. M. Walker, a well-known citizen in Minnesota and Iowa. Our plaintive editor expressed himself thus to Mr. Walker: "Why is it that it requires from seven to ten days for a newspaper or letter to find its way to Chatfield, through the mail, from St. Paul? We do not like to be controversial, finding fault, but it certainly demands inquiry, when it only requires from 24 to 30 hours to make the trip between these points, by way of Winona, the present route of the mail. Again, how does it happen that the Chatfield mail is sometimes carried through to Rochester before we receive it? Mr. Walker will please take notice." Mr. Walker, apparently, did not take notice, since more of the same appeared.

Old files of newspapers from the fifties through the next few decades give the reader an absorbing and vivid picture of the life of the times; give endless material that could be woven into the fabric of an anecdotal history. Those were the years when county superintendants of schools stressed in their printed reports to the public the value of reading, writing and spelling and spoke scathingly of teachers who were delinquent in imparting knowledge of these subjects; when a ten dollar bill was a "Sweet William;" when photographers were "daguerrean artists;" when farmers advertised for lost martingales, for strayed horses and, particularly, for lost oxen. For instance, "one red ox, with staggy horns, white spot on face and white spots on the belly and hips, a long red tail with a white end," happily was recovered, a year after it had strayed, in a township in another part of the county. And a team of working oxen was lost; the near ox, light brindle with a large white spot on the forehead, the off ox, dun color with a small white spot on the forehead; both oxen had brass knobs on their horns and their yoke was a new red one with a patented bow key. Every druggist announced that strychnine was always on hand, presumably for the extermination of animal pests on farms; or perhaps, it has been suggested, because it was used in medical practice then more than now and was hard to get. When a druggist, particularly a physician-druggist, had a good supply he made the fact known. There were fascinating advertisements of Yankee notions, magazines, clairvoyants and hair restorers; patent medicines, painkillers and advice to opium eaters, cancer cures, even as now, and casual mention, not as now, of the outbreak of diphtheria or smallpox in a vicinity. By the early eighties there appeared an occasional advertisement by a physician for a lost instrument: a hydromatic syringe, a perforator used in cases of embryusterulcia, an aspirator used in cases of hydrenleroma phalocele, a myopodiartotican used in cases of myopia and a dentiscalpium used in cases of calcareous precipitation. (The spelling and definitions are as they were printed).

With the coming of the Civil War, when Fillmore County was eight years old and not yet recovered from the panic of 1857, there was much newspaper comment, such as (in 1862), "Ho! for the War! Intervention of England and France. 50,000 more soldiers. Call for a sixth regiment of Minnesota Volunteers;" about enrollment boards, exemptions from service, enlistment of troops and paying of bounties to stimulate recruiting. Although an Olmsted County newspaper commented disparagingly on men from Fillmore County who presented themselves before the Enrollment Board of the district, in Rochester, for exemption, Fillmore County nevertheless was represented with honor in the Union Army in many regiments. Company A of the Second Minnesota Infantry, for example, was made up chiefly from Chatfield; and although the famous Rangers of the county were not in the war, they were on duty within the state. Immediately after the war politics waxed and waned; during the presidential campaign numerous Grant and Colfax Clubs were organized in Fillmore County. There were further notices about bounties and many about collection of pensions. Finally, for the convenience of the veterans, there were medical examining boards, made up of local physicians, of the county bureau of pensions.

Through all the years, from the early fifties on down, there was constant promotion of railroads until finally the Southern Minnesota Railroad and the Caledonia, Mississippi and Western were established. Thereafter, in the late sixties, and as changes and extensions of the rails took place during the seventies, eighties and early nineties, there was increasing prosperity in some localities and there were declining fortunes in others. Many disappointed towns of Fillmore County were left to one side, especially by the Southern Minnesota Railroad. These little settlements, once thriving, founded each in the high hope that it would become the county seat, a shipping point or a manufacturing center like prosperous manufacturing towns in New England, were doomed to become "phantom villages;" a few of them were Beldena, Liberty, Hamilton, Washington, Etna, Carimona, Forestville, Fillmore and Elliota.

(To be continued in the April issue)

President's Letter

Before, during, and even since the war, European nations have borrowed and copied our industrial methods, which were recognized as superior. Now, the political forces of this country are trying to borrow and copy the equally inferior European medical system.

Such a statement as this raises two questions: First, how does the quality of medical care in this country compare with that of European countries having government-controlled medicine? And, second, how does the cost of medical care in this country compare with that of European countries having compulsory health insurance?

Before the war in Germany there was one physician for every 1,307 persons; in England, one to 1,069; and in the United States, one to 767. Up until 1936, for periods of three, five and ten years, heart disease, diabetes and cancer, respectively, increased at least 50 per cent more rapidly in both England and Germany than in the United States. Tuberculosis decreased about one-third in this country, whereas in England and Germany, only one-fourth and one-fifth, respectively. While diphtheria and other infectious diseases experienced a two-thirds decrease in this country, there was only a minimal decrease in England during the same years, and an actual increase of 200 per cent in Germany. Thus health conditions have steadily become worse in Europe.

In the United States, however, health conditions have constantly improved until they now are better than those of any other country with the same population in the world. Further evidence of the excellence of American medicine is seen in the fact that the United States is now the world's center for medical education. It has wrested this distinction from countries with compulsory health insurance.

Enough about quality, what about the cost? The National Resources Planning board found in 1935-36 that consumer expenditures for medical care amounted to less than four per cent of the national income. The Department of Labor, in 1940, stated that the average American wage earner spends $59 annually for his *family's* health; and, of this, only $13 goes to his doctor. And the Department of Agriculture found that families in small mid-western cities with incomes of from $1,200 to $1,750 spend only three per cent of income for physicians' and hospital bills.

Under the Wagner-Murray-Dingell Bill, a person receiving $100 a month pays $4 a month in taxes, while his employer pays another $4, making a total of $8 a month, or $96 a year. When the salary is $300 a month, the costs become $12 a month for wage earner and employer, or $288 a year. Thus, costs under this bill for compulsory health insurance are greater, both to individuals and to the country as a whole.

And what about costs of health insurance in European countries? Let it suffice to say that in Great Britain, in 1906, national and local taxes were equal to one-thirteenth of the national income; whereas in 1930, local and national taxes amounted to one-third of the national income. Furthermore, the cost of social (medical) service in Great Britain increased 1300 per cent during this period of twenty-five years.

From these incomplete data two conclusions can be drawn: first, that, beyond a doubt, medical care under the present American system is distinctly better than it is under the systems of England or Germany where compulsory health insurance obtains, and, second, that medical care under the present American system costs less than it does under the Wagner-Murray-Dingell Bill or under the system in England, where compulsory sickness insurance has existed since 1911.

Perhaps the inference to be drawn is that plans should be promulgated by the medical profession to provide adequate, high-standard medical care at low consumer cost. This is being done in Minnesota and nationally through the medium of voluntary, prepaid medical care projects. Thus advantages and benefits of both systems will be incorporated in the new American system.

Edwin J. Simons

THE USE OF DEMEROL FOR OBSTETRIC ANALGESIA

THE use of demerol (1-methyl 4-phenylpiperidine, 4-carboxylic acid ethyl ester by diachloride) to relieve the pain of parturition was begun rather soon after the introduction of continuous caudal anesthesia. One of the most extensive experiences with this drug for the purpose under consideration, published thus far, is that of Schumann.[2] He reported the results of use of demerol and scopolamine in 1,000 deliveries at the Boston Lying-in Hospital. He declared that the primary purpose in his use of this type of medication was the establishment of complete amnesia. He concluded that this result was obtained in 70 per cent of the cases (uncorrected figure). He demonstrated to his satisfaction that the drug administered by the intramuscular or intravenous route, exerted no depressant effect on either the full term or premature infant. The only untoward effects on the mother were encountered among the group of patients who were given the drug intravenously. With the exception of transient nausea in a fourth of the cases and occasional vomiting no side effects were observed when the drug was administered slowly; that is, if a minimum of two minutes by the clock was taken to inject 2 c.c. of solution containing 100 mg. of demerol.

Irving,[1] also reporting from the Boston Lying-in Hospital, found that complete or nearly complete amnesia was experienced in 70 per cent of 2,446 obstetric patients in labor who received demerol, as compared to 85 per cent of 14,676 patients who received the barbiturates. In both series scopolamine was used concomitantly. Irving expressed especial concern over the development of maternal pulmonary edema. He reported thirty-five cases in the barbiturate group with three deaths or an incidence of one case of pulmonary edema in 419 deliveries. There were two cases of pulmonary edema among the 2,446 cases in which demerol and scopolamine were given or an incidence of one in 1,223 deliveries. Sixty-two per cent of the babies of the patients who received barbiturates breathed spontaneously (without increase in mortality) and 82 per cent of the babies of patients who were given demerol breathed spontaneously.

In one series, the results of which have not been published, demerol was used in about 1,500 obstetric cases. For a short time, early in this study, the drug was available for oral administration only. When given in this way demerol seemed to be disappointing as an analgesic. Administered intramuscularly, however, after a small initial dose of 1½ to 3 grains (0.1 to 0.2 gm.) of barbiturate, it gave fairly satisfactory analgesia in the great majority of cases. The dose was repeated every three to five hours; however, a total dose of 400 mg. or more was seldom used. On occasions when the first dose of 100 mg. had little effect in from thirty to sixty minutes, a second dose was effective. No untoward maternal side effects were encountered. The purpose of the medication in this series of patients was to give a reasonable degree of analgesia rather than complete amnesia.

No definite deleterious effects were noticed on the infants delivered after the use of demerol in this series. A peculiar type of asphyxia, however, occurred about five or six times as follows: The baby was born with good color and cried lustily at once but was found in a few minutes to be pallid and not breathing. Such babies responded in a few moments to administration of oxygen and gentle stimulation and were subsequently normal. There is no mention in the literature of demerol causing fetal asphyxia and the occurrences just mentioned in only about 0.3 per cent of the cases mentioned cannot be attributed directly to the drug.

Demerol alone does not seem to maintain relief of pain for patients who are in hard labor as well as colonic ether or morphine does, but it lacks the depressant effect of these drugs. The spasmolytic action of the drug noted by those who studied demerol pharmacologically is not impressive from casual observation of patients in labor who have received the drug.

All in all demerol seems to be a welcome addition to the armamentarium of the obstetrician for relief of the pain of labor, especially because it seems reasonably devoid of deleterious side effects to the mother and apparently does not depress too much the higher centers of either the mother or the child.

Arthur B. Hunt, M.D.

MEDICAL PREPAYMENT PLANS GIVEN THE "GO" SIGN

THE House of Delegates of the American Medical Association at its December, 1945, meeting instructed "the Board of Trustees and the Council on Medical Service and Public Relations to proceed as promptly as possible with the development of a specific national health program, with emphasis on the nationwide organization of locally administered prepayment medical plans sponsored by medical societies." The term "specific national health programs" might have seemed rather ambiguous, but a "nationwide organization of locally administered prepayment medical plans" made it clear that the House of Delegates wants the prepayment plans on county or state basis to be pushed as fast as possible and their activities co-ordinated by a national organization.

The report of the outcome of the meetings held in Chicago beginning February 13, 1946, appeared in an editorial in the *Journal A.M.A.* for Februray 23, 1946 (p. 494). The editorial restates, in a revised version, the attitude and purposes of the organized profession, and explains what the AMA intends to do about prepayment medical plans in general.

Many members of the profession may have had in the back of their minds that one huge national prepayment medical insurance company was in the offing. This is not the case. What, in brief, has happened is that the Council on Medical Service and Public Relations has established a Division of Prepayment Medical Care Plans, appointed a Director and necessary staff, has drawn up standards for state or county medical care plans and is ready to assist local, county or state medical organizations in establishing local prepayment insurance units to which the Council is ready to give its seal of approval.

State and County Medical Associations have therefore received the word "go" and should take the necessary steps to promptly extend the number and scope of the already existent prepayment medical insurance organizations sponsored by medical societies.

It is well for medical men to bear in mind that prepayment medical insurance plans require the services of businessmen trained in the insurance business. Fortunately, they are ready to aid to the point of taking over on a non-profit basis.

A number of national insurance companies for some years have provided hospital and medical insurance mainly for large groups of employes. The overhead on the writing of individual policies of this sort is high. Even the Blue Cross hospital insurance is largely limited to groups of employes and the same is true of at least some of the medical insurance sponsored by the profession.

Coverage in general is limited to surgical and obstetrical care and, to some degree, medical care in hospitals. This is a good beginning but such insurance should be expanded not only to provide single policies but to include all possible illnesses, catastrophic in character, for the employe's dependents as well as himself. There is good reason to believe that such coverage can be made available at a cost attractive to people of low income.

REPORT OF DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION

Chicago, December 3, 4, 5, 1945

The meeting was held at the Palmer House in Chicago, with 170 of the total number of properly credited delegates (175) present to make this one of the largest assemblies of representation the Association has had.

The report of the Council on Medical Service and Public Relations occupied fifteen pages of the program prepared for the AMA delegates. A supplemental report of equal size was submitted to the delegates during the session. Resolutions as approved by the House of Delegates will appear in the AMA *Journal.* The activities of the Council have been and will continue to be presented through the columns of *The Journal* and through the bi-weekly News Letter, which is mailed to AMA members desiring it.

Members of the Council have been studying problems confronting county and state medical societies, by holding sectional meetings with speakers chosen from local groups and from the central office. Dr. Joseph Lawrence, director of the Washington office, was included at all of the sectional meetings so that he might report and advise on Federal legislation affecting medical service.

To further crystallize the wishes of the profession, two conferences were held immediately before the annual meeting of the House of Delegates. The executive officers of the state medical societies were invited to participate in a round-table conference held at the Headquarters Office. At the conclusion of each conference, resolutions were prepared with instructions that the Council on Medical Service and Public Relations submit them to the House of Delegates of the AMA. The Council complied with their instructions. There were three chief topics for consideration. The first dealt with Federal legislation. The resolutions favored an approval of the Hill-Burton Hospital Bill, which is to provide additional hospital beds where local need is indicated. The Pepper Bill was opposed since it plans to extend the Emergency Maternity and Infant Care program beyond the war emergency and is drawn to provide medical care for children until they reach the age of twenty-one years. Resolutions opposed the President's compulsory health insurance program and the new Wagner-Murray-Dingle Bill, on the grounds that it was the first step to federal regimentation of medicine, that the program would lower the quality of medical service and, further, that a voluntary plan of prepayment medical care on a competitive basis would preserve private enterprise, encourage investigation and raise the quality of medical service. A 14-point program as shown in the December 1 issue of the AMA *Journal*, page 945, was adopted.

The second topic dealt with resolutions recommending that the House of Delegates go on record as favoring a voluntary national prepayment medical service. The delegates approved the instructions which were given to the Council on Medical Service and Public Relations, with the advice of the board of trustees, that such a plan be initiated immediately. At present the Council on Medical Service is exploring several possibilities and is planning to integrate the present existing groups of voluntary prepayment medical service as a nucleus for the National plan. The national organization will then extend into states where new plans are contemplated or where plans do not exist.

The third topic dealt with public relations, an educational program to be extended throughout the country. The first step is to have physicians and surgeons familiarize themselves with the problems of the employer, the employed and the self-employed persons, like the farmer, to learn how better medical service may be given. This is to be done by talking with the patients and helping them to understand the costs involved in providing the modern advantages of medical science and to realize that a voluntary prepayment medical service is less expensive and offers a higher quality of service than the compulsory insurance. It was recommended that the information be extended to leaders of each community.

An address by Major General Paul R. Hawley on the care of the veteran was heard. Dr. Hawley included in his talk a discussion of plans for aiding veterans not only on the local scale but on the national level as well. His talk, which met with the approval of the entire house, appears in the AMA *Journal*, December 22, 1945, page 1192.

It was announced that the next meeting of the House of Delegates will be held in San Francisco July 1-5, 1946, and that hotel arrangements have been completed with the San Francisco hotel association. It is hoped that the fact that the war is over will bring about an increased attendance.

Since 1947 will mark the one-hundredth anniversary of the founding of the American Medical Association, elaborate preparations are being made for the 1947 meeting to be held in June of that year in Atlantic City, N. J.

One of the state delegates offered a resolution to the effect that the Council on Medical Service and Public Relations should be the sole spokesman for the American Medical Association. The resolution was not passed, since it was the opinion of the assembly that a lesser body in the association cannot assume the spokesmanship which rightfully belongs to the House of Delegates.

A new section, to be called General Practice of Medicine, and to be distinguished from the Internal Medicine specialty, was approved for addition to Scientific Assembly.

An important topic of discussion was the recent gift to the American Red Cross by the Army and Navy of 1,250,000 units of dried blood plasma which are being redistributed to all the states in the Union through the individual departments of health. Further discussion of this project will be found in MINNESOTA MEDICINE.

The Delegates to the American Medical Association wish to recommend that members follow carefully the Washington Letter and the Medical Legislation Program in *The Journal* of the AMA.

Results of the election of officers were as follows:

President-elect: Dr. H. H. Shoulders, Nashville, Tenn., Speaker of the House for the last two years.

Speaker of the House: Dr. R. W. Fouts, Omaha, Neb.

Dr. L. A. Buie has been elected to the Judicial Committee and Dr. A. W. Adson has been re-elected to the Committee on Medical Service and Public Relations.

It was learned at the meeting that Dr. George F. Lull, formerly deputy Surgeon General of the United States Army Medical Corps, has been appointed Associate General Manager of the AMA. He began work in his new position on January 1.

CANCER DETECTION CENTERS AND ALLIED CANCER PROJECTS

ARTHUR H. WELLS, M.D.
Chairman of the Committee on Cancer

At a recent meeting of the Committee on Cancer, the standards, rules, and regulations, and the means of establishing Cancer Detection Centers in Minnesota were considered—in line with the program approved by the American Medical Association at its House of Delegates meeting in December and by the Council of the Minnesota State Medical Association at its December 16th meeting. This program is a co-operative venture between the Minnesota Cancer Society and the Minnesota State Medical Association and its component county societies, the Cancer Society underwriting the cost of the clinics where desired, and the medical profession initiating, directing and staffing the clinics. Increasingly large sums of money are being collected by the Minnesota Cancer Society, allotments of which are being made available for County Medical Society cancer projects.

For many years the activities of the American Cancer Society were largely limited to a program of cancer education and cancer research. However, it became increasingly apparent that this program was not complete, and that there was a great need for service to the patient. There developed, as a recognition of this need, the formation of the Service Division of the American Cancer Society. This Service Division is governed entirely by practicing physicians, with representatives from the American Medical Association, the American College of Surgeons, and the American Roentgenological Society. The Service Division is responsible for all projects concerning the patient as a patient, and includes the following specific functions: (1) survey of needs, (2) detection, prevention, or well-person clinics, (3) diagnostic clinics, (4) treatment centers, and (5) care of advanced cancer patients. The American Cancer Society, or its State or local divisions, may not own or operate any clinic, laboratory, hospital, or other facility for the care of cancer patients. The Cancer Society is a benevolent pressure group acting under the constant advice of physicians. All cancer projects financed or aided by the Cancer Society must have the approval of the County and State medical groups.

Three sets of standards, rules and regulations are to govern the establishment and maintenance of Cancer Detection Centers: (1) those of the American Medical Association, (2) those of the State Cancer Committee, and (3) those developed by local County Medical Societies.

The following American Medical Association principles of operation of Cancer Detection Centers are reviewed:

1. Definition: A cancer detection, cancer prevention, or well-person clinic is designed to detect abnormalities, not producing symptoms sufficient to send the patient to the doctor. These clinics do not diagnose or treat diseases.
2. No such clinics shall be established in any community without the approval of the County Medical Society.
3. The examination shall be as complete as local facilities will permit with the exception of biopsy. In all instances this examination shall include a complete history and physical examination.
4. Records may be as complete as desired. They shall in all instances include the abnormal findings.
5. If abnormalities are detected, the patient shall be referred to the family physician for diagnosis and treatment. If there is no family physician, the patient shall be referred to a physician or clinic selected by the patient from a group chosen by the County or State Medical Society. Such reference shall include a complete report of the screening examination.
6. One month after such reference to a physician, the case shall be followed up by letter or social service visit and a complete report of the diagnosis and treatment shall be obtained.
7. Cancer Detection Centers must be located in hospitals approved by the American College of Surgeons.[1]

The policies recommended by the State Committee on Cancer follows:

1. A Cancer Committee shall be appointed in each interested County Society.
2. The Chairman of the Cancer Committee of each County Society shall be charged with the responsibility of interesting hospital authorities and hospital medical staffs in his community in setting up clinics. He is also responsible for maintenance of standards in established clinics.
3. The hospital staff shall select a special committee to be responsible for setting up the clinic—to determine how much space is needed, how much money from the Minnesota Cancer Society will be needed to finance the project, to select the personnel and physicians to staff the clinic and to assign their duties.
4. The Minnesota Cancer Society shall provide uniform medical history and physical examination forms to be drafted by the State Committee on Cancer for the use of examining physician. This Society shall also provide advertising, clerical help, and telephone facilities for aiding in arrangement of appointments, receptionists, and the maintenance of records, as requested and approved by the County Medical Society or its Cancer Committee.
5. The local County Medical Society must approve of every clinic before it is established.
6. Clinics shall be free to all persons coming in for examination.
7. A nurse may be employed to take the preliminary case history, but this must be checked and enlarged upon later by a physician.
8. An internist and a surgeon shall examine each individual patient for cancer, its precursors, or other ailments, with particular attention to the more common and accessible sites of cancer.
9. Physicians shall donate their services without charge.

At the outset, it is hoped that trial clinics will be set up in the three largest cities: Minneapolis, Saint Paul and Duluth. However, as soon as it is practical and

of the
Minnesota State Medical Association
George Earl, M.D., Chairman

ORGANIZED AGITATION FOR SOCIALIZED MEDICINE TOUCHED OFF AT CONFERENCE

Using Minnesota as trial ground, proponents of a program of federally-administered compulsory health insurance got together for a "Health Workshop" Conference in St. Paul at the Lowry Hotel February 6 through 9. At closed sessions leaders in the National Farmers Union, the American Federation of Labor, the Congress of Industrial Organizations and the Railroad Brotherhoods, met to find the most effective way of spreading the gospel of national health insurance.

Delegates were invited in from Minnesota, Wisconsin and the Dakotas to "unite and demand the political action necessary to improve this nation's health care and standards."

Conference Turns Out "Technical Consultants"

During the four-day sessions, confined to representatives of the sponsoring unions, the delegates were briefed and provided with folios of information so that they might go back to their home states as "technical consultants" and set up interim committees for the purpose of educating the people to the need for improving health facilities. It is hoped apparently that as a result of a carefully planned campaign of education, the program for socialized medicine might gain favor and that more people would put pressure on elected officials to support legislative measures of the Wagner-Murray-Dingell brand. It was decided at the meeting that there will be a series of follow-up meetings, comparable to this one, which will take in more localized groups.

Some of the speakers were loudly critical of the medical profession; others tempered their comments. A couple of the speakers were outspoken in their praise. It was voted to invite the representatives of the medical, dental and allied health professions to sit in and be heard at the follow-up meetings in the various states.

National Farm Union President Sounds Keynote

James G. Patton of Denver, president of the National Farm Union, made the keynote address on the evening of the eighth. His punch lines were that President Truman's five-point program, submitted to Congress last November, was fine, but not drastic enough, and that it was high time the "working" farmers and "working" laboring men took political action to insure a "progressive program across the board to guarantee every man, woman and child needing it a free education, free medical care and a decent standard of living."

Obstructionists, such as congressmen and governors, who are against social legislation, said Mr. Patton, must be done away with. Throughout his talk, Patton stressed that the program being launched at the conference was to be one of action. "The lack of medical care," he declared, "is going to be ended *now* and not 25 years from now!"

This health workshop conference was planned back in June of last year, when Mr. Patton and Surgeon General Thomas Parran met at Washington. At that time the facilities of the U. S. Public Health Services were offered to further a universal program for adequate health care for all people with the emphasis on those in the $1,000 or less income bracket, *provided* that other federal agencies in the health field would also cooperate in the venture.

Present at the health workshop conference to help work out the details of the health education program were specialists from various governmental agencies, including the Department of Agriculture, the U. S. Public Health Service, the Federal Housing Agency, the Social Security Administration and the Department of Labor.

SOCIAL SECURITY COSTS IN U. S. RISING RAPIDLY

With the government providing more and more services to citizens, the cost of the social security program in this country is rising steadily. Not that this increased spending is all the result of an actual improvement in services offered—the lion's share of the social security budget is being turned over to the thousands of employes in the bureaucratic honeycomb.

The latest service which some would delegate to the government is that of providing health insurance, such as is called for in the Wagner-Murray-Dingell Bill. And although no tax provisions are emboided in the context of the bill, it stands to reason that the program will have to be financed through an additional tax burden on the American people, all of which will contribute another substantial hike to the cost of social security.

This is the social security picture today—a large and ever-growing financial drain on the budget by bureaucrats, plus the prospect of a large additional drain.

According to conservative estimates, it would take at least 600,000 additional salaried government employes to administer the compulsory health insurance program of the Wagner-Murray-Dingell Bill. This army of bureaucrats will draw on an average of $3,000 a year each, according to the present average federal salary scale.

According to Representative Charles W. Vursell (Illinois, Republican), there are now a total of 1,141 bureaus in the federal government, which employ 3,649,383 persons. By adding the salaries of the workers who will be needed to manage a federal health insurance program to the present huge payroll, an estimate can be obtained of what the total costs will be should the Wagner-Murray-Dingell Bill become law.

HEALTH BENEFIT PROGRAMS ESTABLISHED THROUGH COLLECTIVE BARGAINING

During recent years, an increasing number of unions are having health benefit plans included in the terms of their agreements with employers. A report of this development, summarized in the August, 1945, *Monthly Labor Review*, published by the Bureau of Labor Statistics of the U. S. Department of Labor, indicates a significant trend in labor circles toward making medical coverage a part of negotiated contracts. Some of the more recent health benefits have been negotiated in lieu of wage increases which could not be obtained under the wartime wage stabilization program.

Details of three types of health benefit programs, determined by their method of administration, are set forth in the article: those administered entirely by the unions, those administered jointly by union and employer, and those administered through private insurance companies with the insurance company assuming responsibility for eligibility of claims and payment of benefits.

In the main, health benefit plans provided under union agreements include weekly disability benefits usually ranging from 50 to 60 per cent of regular earnings; many plans provide surgical benefits ranging from $100 to $175; and hospital expenses ranging from $4 to $5 a day for 31 days, are usually allowed for any one continuous disability. A few plans allow specified payments for doctors' services up to a maximum of 50 visits for any one disability, which usually begins with the first treatment in the case of accident and the fourth, in case of illness. As might be expected, benefits tend to be higher under plans negotiated in industries having relatively high wage scales.

According to the article, the enlarging of health-benefit programs to cover more workers and provide more services, and the solving of administrative difficulties, such as the problem of the length of time to be covered during temporary lay-offs, seasonal slack periods and leaves of absence, remain to be worked out in future negotiations.

AMERICAN ACADEMY OF PEDIATRICS EVALUATES PEPPER BILL

After carefully evaluating the Pepper Bill, the "Maternal and Child Welfare Act of 1945," which would provide grants by the federal government to the states for providing medical services to mothers and children (up to the age of 21), the American Academy of Pediatrics has adopted a resolution setting forth specific criticisms of the bill.

The first criticism which the Academy notes is that the bill as now written states that services and facilities furnished under the state plans are to be available to all mothers and children who elect to participate in the benefits and therefore denies the states' rights to determine eligibity.

The Academy of Pediatrics does not favor the use of federal funds for those able to provide medical care from their own resources.

The Academy notes further that the bill excludes fee-for-service as a means of paying practitioners for their services, makes inadequate provision for paying groups of physicians or institutions for professional services and does not prevent professional personnel groups or institutions from accepting supplemental payments.

Issue is taken with the endorsement by the bill of the Children's Bureau as the administrative agency of the National Health program, as outlined, without the proper assurance of the program's integration with other health activities of the federal government.

Issue is taken also with the definition of federal or state advisory committees as regards personnel, method of appointment, advisory and policy-making roles or manner of giving authority to the record of consultations with and recommendations to the administrators.

It is noted that no provisions are made for varying the remuneration for services according to the differing costs from state to state; nor is there any provision for the prevention of arbitrary requests on short notice by the federal administrative agency for reports from the state health agencies or from the practitioners. The provisions for handling claims are unsatisfactory as are the specifications regarding adequate dental care.

Research and Education Not Provided For

The Academy feels that one of the most serious errors of the bill is that it fails to make adequate provision for the protection of the well-organized teaching services and for the support and encouragement of research pertaining to the improvement of maternal and child health services and medical care. On these, the Academy states, the future of the quality of medical care is dependent.

The final criticism is aimed at the lack of assurance in the bill that state plans shall not expand too rapidly for the available administrative and professional personnel and resources. For these reasons, the Academy concludes in its resolutions, the Maternal and Child Welfare Act of 1945 does not represent the best forms of legislation for the purpose for which it was written.

For those considering proposed legislation, the Academy directs attention to its fact-finding study of child health services, now in progress, which at its conclusion, should assist in the development of sound programs at state levels based on demonstrated needs.

Pending the completion of this study, it is recognized that urgent need exists in some states that should be met immediately. To this end the Academy recommends that additional federal funds be made available for grants-in-aid to the states under existing Maternal and Child Health and Crippled children's programs under the Social Security Act.

FELLOWSHIP GIFT RECEIVED

A gift of $25,000 to the University of Minnesota Medical School has been received. The money is to be used to provide five graduate medical fellowships of $1,000 a year each, covering a five-year period.

Veterans of World War II are to receive the fellowships, which may be used for study in any recognized field of medicine.

AERIAL CLINIC IN ALASKA

In Alaska where "everybody flies" among the air-age projects under way is the establishment of an aerial medical clinic. Doctors and dentists are outfitting a plane with x-ray equipment and equipment for minor surgical work. The medical men don't intend to perform major operations on the spot; instead, when necessary, the patients are to be flown to the nearest town with hospital facilities.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Bldg., Saint Paul, Minnesota

Julian F. DuBois, M.D., Secretary

TO THE MEMORY OF MAX WILLIAM ALBERTS, M.D.

We were all shocked to learn that one of our members, Dr. Max Alberts, died suddenly at the age of forty-five from a coronary lesion, on June 11, 1945. Though we were aware of the fact that he had been annoyed by precordial distress, none of us appreciated his critical condition, nor did Doctor Alberts permit himself to be an invalid. On the fatal day, in spite of pain, he reported at the hospital, performed a laparotomy and succumbed on his way home while driving his car.

Max, as we all knew him, had served with us as a member of the State Board of Medical Examiners for a period of eleven years, beginning his service on May 9, 1935. During this time we had learned to know him, both professionally and socially. Professionally he had made satisfactory progress. He was liked by his colleagues and developed an enviable surgical practice. His decisions on the Board were fair. He showed his understanding of human frailties by being inclined to soften or lessen the maximum penalties for violators of the medical codes and laws.

Max gave generously of his time to medical affairs and served on numerous city, county and state committees. He took his professional work very seriously, but he did enjoy relaxing. He appreciated his social contacts, enjoyed discussing sports and politics, on both of which subjects he was well informed.

Though Max's demise is our loss, it is not comparable to the loss experienced by his wife, son and daughter. We have lost a colleague, a regular guy whom we shall always remember; they have lost a husband and father who loved his family and whose family loved him. Max has not lived in vain.

MINNESOTA STATE BOARD
OF MEDICAL EXAMINERS.

Minneapolis Ex-convict Sentenced to One Year Term for Violating Basic Science Law

State of Minnesota vs. Harry C. Chappell

On February 8, 1946, Harry C. Chappell, forty-eight years of age, 2239 Cole Ave. S.E., Minneapolis, was sentenced by the Hon. Arthur W. Selover, Judge of the District Court, to a term of one year in the Minneapolis Workhouse. Chappell was sentenced for representing himself as a doctor in violation of the Minnesota Basic Science Law.

Chappell was arrested on February 6, 1946, by Detectives Lillejord and Henseler of the Minneapolis Police Department following an investigation by Inspector Bernath and Captain Mullen of the Minneapolis Police Department, and representatives of the State Board of Medical Examiners. Chappell, who has no medical training of any kind, had telephoned at least two women who had inserted advertisements in the Sunday *Minneapolis Tribune* of February 3, 1946. The women were seeking stenographic work and Chappell, in answering the advertisements, stated that he was a doctor and that he was about to open an office in the Masonic Temple Building, Minneapolis. One of the applicants went to Chappell's home address where he insisted that she submit to a physical examination as a prerequisite to being given employment. The applicant objected to a physical examination on the ground that she had been examined by her family physician in December and found to be in good health. Chappell insisted on the physical examination and had the applicant remove her clothing. Following the examination the applicant informed her parents of what had taken place and the matter was immediately reported to the Hennepin County Medical Society and to the Minnesota State Board of Medical Examiners.

Chappell has a long criminal record dating back to June, 1922, at which time, he pleaded guilty in the District Court of Hennepin County to robbery in the third degree. For that crime Chappell served a term in the St. Cloud Reformatory. In May, 1930, Chappell was sentenced to a five-year term in the North Dakota State Prison for burglary in the third degree. He served three years and three months of that sentence. In March, 1934, Chappell was sentenced to a term of two to fourteen years in the District Court of Ramsey County, Minnesota, for the crime of indecent assault. Chappell served nine years of that sentence.

In June, 1944, Chappell was sentenced in the District Court of Hennepin County to a term of one year in the Minneapolis Workhouse for attempted carnal knowledge involving a fifteen-year-old girl. Chappell stated, when questioned by Minneapolis Police officers, that his only occupation outside of serving more than twenty years in various prisons, was that of a bell-hop at several Minneapolis hotels. Chappell admitted that he had no intention of attempting to practice medicine and attributes his present difficulty, as well as two of his previous encounters, to "liquor and sex."

Michigan Physician's Minnesota License Revoked

Revocation of the License of Elmer J. Hagenbaugh, M.D.

The Minnesota State Board of Medical Examiners, at its regular meeting on February 8, 1946, revoked the license to practice medicine held by Elmer Jasper Hagenbaugh, M.D. Dr. Hagenbaugh was convicted on May 10, 1945, of the crime of manslaughter, in the Circuit Court of Calhoun County, Michigan. The criminal charge followed a criminal abortion performed by Dr. Hagenbaugh. Dr. Hagenbaugh was sentenced to a term of five to fifteen years in the Michigan State Prison at Jackson, Michigan, and is serving his sentence at the present time. Dr. Hagenbaugh was found guilty by the Board of immoral, dishonorable and unprofessional conduct in connection with the Michigan offense.

Dr. Hagenbaugh was practicing at Athens, Michigan, at the time of his conviction. On August 11, 1944, Dr. Hagenbaugh was convicted in the Superior Court of Elkhart County, Indiana, of the crime of abortion and was sentenced to a term of not less than three, nor more than fourteen years in the Indiana State Prison and fined the sum of $1,000. Upon the payment of the fine the Court suspended the prison sentence. Shortly thereafter Dr. Hagenbaugh moved from Elkhart, Indiana, to Athens, Michigan.

Dr. Hagenbaugh was born at Sherwood, Michigan, in 1864. He graduated from the Toledo Medical College in 1905, and was licensed in Minnesota, in 1909, by reciprocity with Illinois. Dr. Hagenbaugh practiced medicine for a short time in 1909, at Rochester, Minnesota, and then moved to Elkhart, Indiana.

License of Minneapolis Physician Suspended for Five-Year Term

Revocation of the License of Harold E. Harbo, M.D.

On February 8, 1946, the Minnesota State Board of Medical Examiners suspended, for a period of five years, the license to practice medicine held by Harold E. Harbo, M.D., who formerly maintained an office at 4 West Lake Street, Minneapolis. Dr. Harbo was found guilty by the Board of immoral, dishonorable and unprofessional conduct in connection with an abortion performed on a thirty-two-year-old unmarried Minneapolis woman in April, 1945.

An investigation was commenced by the Minnesota State Board of Medical Examiners when it was learned that the patient was hospitalized with an infection following the alleged abortion. The patient gave a statement in which she claimed that she consulted Dr. Harbo for the purpose of having him perform an abortion upon her and that he advised her to get a room and that he would have someone come to the room for the purpose of doing the abortion. The patient stated she paid the sum of $150 but declined to identify Dr. Harbo as the person who came to her room and performed the abortion. Dr. Harbo appeared in person before the Board and admitted that he performed the abortion.

Dr. Harbo was born at LaCrosse, Wisconsin, in 1892. He graduated from the University of Minnesota in 1921 with a Bachelor of Medicine Degree. He received his Doctor of Medicine degree in 1922. He was licensed in Minnesota by examination in 1921.

Minnesota Academy of Medicine

Meeting of December 12, 1946

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 12, 1945. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 by the President, Dr. A. G. Schulze.

There were forty-six members and two guests present.

Dr. E. M. Jones read the following memorial to Dr. Max Alberts and a motion was carried that this be spread on the minutes of the Academy and a copy sent to Dr. Alberts' family.

MAX WILLIAM ALBERTS
1899—1945

Max William Alberts was born at Berlin, Wisconsin, October 28, 1899. He attended the public schools at Berlin, Wisconsin, before entering Ripon College where he received his preliminary college work. He entered the Medical School at the University of Minnesota and received his degree in Medicine in 1923.

He served his internship at St. Joseph's Hospital of St. Paul, Minnesota, and on completion of this service, became associated with Dr. W. C. Carroll in Saint Paul as surgical assistant.

In July 1925, he married Lola Schultz, who, with two children, a son, William, and daughter, Mary, survive.

Dr. Alberts always exhibited a most sincere interest in Medicine and took an active part in the proceedings of the medical societies to which he belonged. He was a member of the American Medical Association, the Ramsey County Medical Association, and the Minnesota State Medical Association. He was also a member of the Western Surgical Association, the American College of Surgeons, the Minnesota Academy of Medicine, and the St. Paul Surgical Society. He was a member of the Minnesota State Board of Medical Examiners, a clinical assistant in Surgery on the Medical Staff of the University of Minnesota, and was on the Board of Trustees of Ripon College.

Dr. Alberts had no particular hobby, but he was very much interested in sports, especially baseball and football, and had many close friends among the coaches and players.

Dr. Alberts was a tireless worker, and was always willing and ready to lend a helping hand when necessity arose. His confreres in St. Paul and the members of the Minnesota Academy of Medicine have lost a good friend and a good surgeon.

The election of officers followed and the following were elected to serve for the year 1946:

President .... Dr. S. E. Sweitzer, Minneapolis
Vice President ...... Dr. E. M. Hammes, Saint Paul
Secretary-Treasurer .... Dr. A. E. Cardle, Minneapolis

The scientific program followed.

THE SIGNIFICANCE OF BLEEDING FROM THE RECTUM

JAMES K. ANDERSON, M.D.
Minneapolis, Minnesota

Bleeding from the rectum is one of the commonest complaints presented by the patient consulting the proctologist. Mummery,[4] in various articles, states that bleeding may result from almost any bowel complaint, and that mistakes and difficulties in diagnosing the source of bleeding from the rectum are many; in fact, more frequent than in other forms of hemorrhage. To the patient, bleeding from the rectum usually means one or two things—hemorrhoids and cancer. Too often the diagnosis of hemorrhoids is accepted by the physician without further investigation and this is one of the common pitfalls in diagnosis or lack of diagnosis that we see in malignant lesions of the rectum and rectosigmoid. A noticeable number of individuals with malignancy coming into our office have been subjected to a hemorrhoidectomy during the preceding few weeks or months, because of bleeding from the rectum; these patients had hemorrhoids as well as another lesion.

Sources

The sources of blood passed by rectum are multiple as well as the lesions responsible for the bleeding.

Any ulcerative, proliferative, or inflammatory lesion of the mucosa of the bowel may be the source of the blood, and blood may come from any portion of the alimentary tract. It is fairly easy to distinguish blood coming from the small intestine, as this blood is partly digested in the intestine and will be dark or have the ordinary characteristics of melena, although I have seen two patients with severe hemorrhage from the rectum from a gastric or duodenal ulcer, where the blood passed was bright red and in bright red clots, having come through the entire tract in a very short time. Blood coming from the large intestine is not so easily diagnosed as it is often little changed in characer and may be confused with blood originating in the rectum. As a rule, however, it is mixed with stool and mucus and is not so bright. Any blood remaining long in the colon or rectum becomes dark.

Blood coming from lesions in the rectum, carcinoma, polyps, ulcers, internal hemorrhoids, is usually bright red and not mixed with stool. Hemorrhoidal bleeding usually comes with and after the stool is passed, but internal hemorrhoids may be irritated or abraded by the passage of the stool and this blood accumulates in the rectal ampulla to be passed some time later in a changed, clotted and darkened form and so suggests blood from higher in the tract.

Thesis read before the Minnesota Academy of Medicine.

Severe hemorrhage from diverticulitis is fairly common. In my experience, the blood passed is thin and dark, not clotted, and in some quantity. These hemorrhages come suddenly and may be serious but usually are self-limiting and come in attacks. At times the bleeding is preceded by dull colonic pain. These patients are usually over 40 and obese. Diverticulosis occurs in about 5 per cent of individuals over 40.

Nothnagel's[5] table, made many years ago, gave the common causes of rectal hemorrhage as: hemorrhoids, dysentery, typhoid and carcinoma. He stated that small quantities of pure blood either light or dark suggested the rectum or sigmoid as the source. When blood forms a coating on the stool, the cause is in the lower part of the bowel. On the other hand, if the blood is mixed with the stool, the source is probably high and from the small bowel.

Landsman[3] states that the presence of a constitutional disease of some nature has a decided bearing on the possibility of bleeding from the rectum, notably tuberculosis, syphilis and hepatic disease. Primary tuberculosis is very rare, but secondary infection from the lungs is common. In 1230 autopsies in the Royal Victoria Hospital, but two gave evidence of primary involvement in the bowel, while 285 were secondary to tuberculosis elsewhere. Syphilis may involve the lower portion of the intestinal tract as chancre, or in its secondary or tertiary manifestations as mucous patches, condylomata, fissures, ulcers, proctitis, gummata, and strictures, besides congenital syphilitic lesions principally of the anus which give rise to ulcerations. Of these, chancres and gummata are infrequent; the others are fairly common. Hepatic disease, though rare, may be a fruitful source of rectal bleeding because of its mechanical and other effects in bringing about pathological conditions of the rectum.

Hence, the character of the blood expelled is not so important as was formerly taught. Merely because the patient loses blood from the rectum is no proof that the source of it is in that organ. It may come from any part of the intestinal tract and its color is by no means infallible evidence of its origin despite the fact, which is often accepted, that if the blood is dark it comes from high up, whereas if it is red, the lesion which causes it is low down. Blood coming from high up is indeed dark, clotted and otherwise altered, but only if retained in the bowel a sufficient time. If it is expelled before these changes have had time to occur, it will be bright red. Conversely, blood from low down may be retained in the rectal ampulla long enough to become dark and possess all the characteristics of blood coming from higher up. We may even have at times both liquid and clotted blood from the same lesion at the same time, whether situated high or low, thus tending further to confuse the issue. So, we cannot draw any positive conclusions from this circumstance until the findings have been confirmed by more reliable data, a careful history, and proctoscopic and x-ray examinations.

Postoperative bleeding or hemorrhage following anorectal surgery occurs in a small percentage of cases. This is usually due to a slipped suture if within twelve hours, but may occur up to fourteen days due to slough and vessel erosion, and prove embarrassing. The diagnosis and treatment is evident.

Chronic ulcerative colitis is one of the common lesions producing bleeding. This bleeding may be slight or profuse, is usually thin and mixed with stool and mucus, and accompanied by frequency of movements. Amebic and bacillary dysentery are also seen and give somewhat the same symptoms. Factitial proctitis is commonly seen following radium implantation in the cervix. This lesion is seen on the anterior rectal wall as a telangiestasis. The bleeding from this lesion may be brisk but is usually noted in small amounts in the stool.

In cases of hemorrhage from the rectum, the expelled blood should be examined soon after its passage, if possible, and before further chemical changes have occurred. This may give some indication of the source.

Quantity

The quantity of blood lost depends in great measure upon the size of the lesions, its character, and the extent of the destructive process. Carcinoma of the colon or rectum, multiple polyposis, ulcerative colitis, the dysenteries, and diverticulosis, show extensive areas of involvement and the pathological process inclines to deep destruction rather than to spontaneous recovery; hence, bleeding from such sources is naturally more severe and persistent, and the expelled material more often contains an abundance of mucus, pus, and pieces of tissue, in contradistinction to such innocent causes as hemorrhoids, single polyps, prolapse, et cetera, in which the blood will be found to be unmixed and show no products of tissue destruction. These lesions may also cause interval bleeding. It may be accepted, then, in a general way, that mixed blood points toward serious conditions, though the converse of the proposition does not invariably hold true, for unmixed blood does not necessarily predicate benign lesions.

When there is any pathological condition of the bowel which has a tendency to bleed, any increase in the intra-abdominal pressure, due to straining, vomiting, or defecation, may initiate it. However, the sudden appearance of a large hemorrhage, without any previous history of rectal disturbance and independent of any bowel movement, is quite characteristic of some cases of carcinoma of the rectum. One occasionally obtains a history of a similar onset in hemorrhoids or polyps, but close questioning will nearly always reveal a distinct interval history of rectal symptoms preceding the hemorrhage.

Perverted function of the bowel and any co-existing bleeding have a definite relationship to each other. When there is persistent constipation, the force and straining required to expel the stool are liable to cause injury to the mucous membrane, aside from any medical or chemical means used to help secure an evacuation. In an impaction the same factors operate with the further addition of a possible necrosis due to pressure of the hard, dry fecal masses on the delicate mucous membrane. When the stools are abnormally frequent, they are likely to contain blood from the lesion which causes the diarrhea, if not from the straining and tenesmus set up by the discharges.

Zobel[6] states that bleeding from gastric and duodenal ulcers and cancers is the usual cause of tarry stools. But these may also follow severe hemorrhages from the nares, lungs, esophageal varices, or typhoid ulcerations. Portal obstruction from any cause, acute yellow atrophy of the liver, purpura, hemophilia, leukemia, aneurysm, mesenteric thrombosis and scurvy may also be causes. Carcinoma of the colon seldom produces profuse hemorrhage and hence not tarry stools, but gross and occult blood.

Profuse bleeding originating in the rectal ampulla is usually from an ulcerating carcinoma of the rectum or rectosigmoid, a detached polyp, or sloughed hemorrhoid. The passed blood is bright and may contain clots mixed with stool.

There is a group of lesions and diseases of particular interest to the internist in which there is bleeding from the rectum in varying amounts and color, either free or mixed. They are: gastric and duodenal ulcers, yellow fever, septicemia, endometriosis with rectal involvement, pyemia, malaria, dengue, typhoid, jaundice, abdominal injuries, intestinal hemorrhages not due to tuberculous ulceration but to tuberculous pulmonary disease, sudden diarrheal attacks with bloody mucus which occur in exophthalmic goiter, arsenic and phosphorus poisoning, cancer of the small intestine, intestinal parasites, sclerosis of the intestinal vessels, chronic nephritis and acute enteritis.

The most common causes of bleeding from the rectum in children are polyps, prolapse and anal fissures, although well-developed hemorrhoids are occasionally seen. Proctitis, colitis, and intussusception also cause bleeding. Blood and mucus passed by a child under one year of age is almost diagnostic of an intussusception. Foreign bodies (thermometers, pencils, et cetera), introduced into the anus, are also fairly common causes of trauma and resulting bleeding. Meckel's diverticulum must also be considered, the blood in this case being dark and mixed with stool.

Diagnosois

The diagnostic problem involved in bleeding from the rectum is based on an adequate history and careful anoscopic, proctoscopic, and roentgenologic examination.

I feel that the examination should begin from below, with a digital examination followed by a short anoscope—the type with which the physician is familiar; then the electrically lighted proctoscope inside for at least 20 to 35 cm., if possible, examining every inch of the mucosa and looking behind the valves of Houston. In many cases, due to angulation or spasm, it is impossible to examine farther than 16 to 18 cm. without anesthesia. If blood is seen to be coming from beyond the proctoscope, or no source of bleeding is found for the distance examined, a barium enema is indicated which may reveal polyps, carcinoma, or diverticulosis. The openings of rectal and low sigmoidal diverticula are occasionally seen. If proctoscopic examination and barium enema are negative, a gastro-intestinal study is necessary. X-ray examination for carcinoma of the rectum is often misleading. These instrumental examinations are not difficult if proper equipment is on hand for the removal of blood and any liquid stool found in the bowel, and certainly should be done where any blood is passed. The more common cases of bleeding will be diagnosed and the more obscure ones will be gradually approached by the process of elimination. Individuals with severe hemorrhage may be proctoscoped at once if the general condition permits, but the roentgen examination may have to be postponed until the bowel can safely be prepared properly by catharsis or enemata. Fortunately, in most of these cases the bleeding will stop of its own accord and in a few days will permit a complete study. Recurrence, of course, is most likely.

I would like to cite a case of a rather unusual type of rectal hemorrhage which came under my care.

This man, aged forty, a traveling salesman, was out in the western part of the state. Following a bowel movement he passed considerable bright red blood and reported to a local physician who examined him and gave him some suppositories. He started to drive east and at several towns stopped at toilets and each time passed only bright blood in some quantity. He also visited several other physicians who gave him similar treatment.

I saw him about six hours after the bleeding had started and he again had a rectum full of bright blood. This was removed by suction and I could see the stump of a polyp in the rectal ampulla with a pulsating vessel. On close questioning, he stated that he had felt something protrude from the anus at the time he had first noted the blood and when he wiped himself he felt something snap and noted a piece of meaty tissue on the paper. The pulling off of a pedunculated polyp or adenoma may often happen, but this is one case that was very definite and might have proved tragic.

I would also like to report one typical case of severe hemorrhage from the bowel as the first evidence of a rectal carcinoma.

This man, aged fifty-seven, on September 18, 1943, had three severe hemorrhages from the rectum. These, of course, frightened him and he reported for examination. On close questioning, he admitted that for several months he had noted a red stain in the toilet bowl but never any gross bleeding. There had been no weight loss, but some bowel habit change. He also knew that he had hemorrhoids and had considered these the source of the bleeding.

Treatment

Surgical treatment is indicated in the majority of these cases to remove the source of the bleeding, whereas others require medical treatment, rest and diet.

Summary

In summary, I would say that bleeding from the rectum is a common symptom. Lesions and diseases are multiple. Diagnosis may be evident or very difficult to establish. Careful history, ocular and x-ray examinations will usually reveal the cause. Hemoglobin estimation will reveal the extent of the blood loss.

A plea is made for careful proctoscopic examination of the rectum and rectosigmoid, especially when hemorrhoids or evident anal pathology which commonly causes bleeding exists, and a complete gastro-intestinal study with the x-ray when lesions are not found by ocular examination.

Discussion

Dr. L. G. Rigler, U. of M.: It may seem paradoxical for a roentgenologist to agree with Dr. Anderson about the lack of accuracy in the roentgen examinations of the rectum. I am amazed at how many patients are sent in for a barium enema study without previous proctoscopic examination when a lesion in the rectum is suspected. It is an extremely difficult thing to demonstrate such lesions and roentgen diagnosis is in doubt because this is one portion of the colon where a good filling is not obtained. There are, of course, a few cases in which proctoscopy and sigmoidoscopy are impossible and there even rectal examination is doubtful, but aside from these, when one is dealing with a lesion within reach of the proctoscope or the finger, I think it is better to get the direct determination of the lesion rather than by an indirect procedure such as with the roentgen examination.

Determination of a source of bleeding from the gastro-intestinal tract is one of the most difficult things we have to encounter. I don't know whether it is commonly realized how many patients there are in whom the source of bleeding is never ascertained and that includes the autopsy examination. One of these sources which is difficult to explore is the small intestine and lesions, therefore, are commonly overlooked in this area. In those cases in which there is persistent blood and all of the usual examinations are negative, including x-ray studies of the stomach and duodenum and colon, a very vigorous effort to investigate the small bowel should be made. I am sure that some of my most flagrant errors have been in this field of endeavor. In recent years we have been using the so-called small intestinal enema—a tube is introduced into the duodenum and 1000 c.c. of barium mixture is quickly put into the small intestine through this tube. A sufficient distension and visualization of the small bowel is produced in this way so that gross lesions at least can readily be determined.

I am sure that every radiologist has a feeling of comfort about the lowel bowel if there is a proctologist available so that he can determine some of the things which it is difficult to elucidate by x-ray examination.

Dr. E. M. Jones, Saint Paul: A few years ago I saw a man forty years of age, who presented a clinical picture typical of acute diverticulitis of the sigmoid. He had a temperature of 101°, leukocytosis, with pain and tenderness in the lower left abdomen. He also had rectal bleeding. He was hospitalized, and after a few days an x-ray examination of the colon revealed diverticulitis of the sigmoid.

About a week after admission, a proctoscopic examination was made, and no source of the rectal bleeding was found. The patient insisted on leaving the hospital, but he was advised to return for another x-ray study of the colon.

A few months later I was called to see him again and found that he had been operated upon, and, because of the extent of the lesion, a colostomy was the only thing that could be done.

I cite this experience to emphasize the necessity of being most suspicious of the presence of malignancy when there is bleeding from the bowel, even though the clinical picture is that of an inflammatory process.

Dr. Anderson, closing: The only thing I would like to add is that I had two slides made to use in this discussion. I appreciate the discussions of the men this evening.

These slides show the common and less common lesions producing rectal bleeding.

Lesion Producing Rectal Bleeding

Less common:
- Submucous lipoma
- Submucous fibroma
- Leukemia
- Purpura
- Intussusception
- Foreign body
- Typhoid fever
- Malaria
- Hepatic disease
- Drugs
- Parasites
- Endometriosis
- Factitial proctitis

Common:
- Internal hemorrhoids
- Anal fissure
- Anal fistula
- Rectal fistula
- Rectal adenomata
- Carcinoma—rectum and colon
- Colitis—
    - Ulcerative, idiopathic
    - Amebic
    - Bacillary
- Proctitis
- Diverticulosis
- Prolapse
- Trauma
- Postoperative

VIRUS ASPECTS OF CARCINOMA

ROBERT G. GREEN, M.D.
University of Minnesota
Minneapolis, Minnesota

Cancer research from a virus viewpoint has as yet attracted the efforts of relatively few investigators, but an increasing interest in the possible virus causation of carcinoma, as well as of tumors in general, has been apparent during the past ten years. Viruses have now been shown to be intimately associated with the tumor-cancer problem, and the consistent presence of viruses in certain malignant growths must finally be resolved to a role of causation or definitely relegated to a position of simple association. Comparatively little effort has been expended on the direct investigation of human cancer from the virus viewpoint or from other basic approaches. Physiological, virological and immunological studies on human cancer are very limited. Most investigations in the field of cancer research are conducted on tumors of animals and birds.

Viruses are now becoming one of the more important aspects of cancer research. From the information at present available on such malignant tumors as the carcinoma of rabbits that originates from the Shope papilloma and the breast carcinoma of mice that is stimulated by the presence of the Bittner virus, the filterable viruses must at least be considered biological carcinogenic agents along with coal tar and certain refined chemical compounds. Viruses have a broad distribution among animals and human beings, and some species seem to lurk for long periods or even a lifetime within tissues without producing apparent symptoms. The distribution of viruses and their tumor-producing potentialities point out the viruses as a possible factor in the ultimate causation of most malignant tumors. If, however, viruses should be the basic cause of all or some cancers, the problem still is not a simple one. Hereditary susceptibility, hormonal influences and nutrition all seem to play an important role in the final appearance of the malignant cell.

Many benign and malignant tumors of animals and birds have now been described that have an associated virus and can be reproduced by injection of the virus into the specific animal host. A virologist does not hesitate to accept a virus causation for such tumors as the rabbit papilloma, the oral papilloma of dogs, or the Rous tumor of chickens. However, the ease with which cancer can be produced by the application of chemical agents, and the apparent absence of viruses in cancer thus artificially produced reacts to discredit a theory of virus causation. On the other hand, it cannot be said that the presence of a virus in any tumor has at this time been absolutely disproved. Failure to transmit a tumor upon limited trial under specific conditions does not necessarily mean that an infective agent is not present. Such a situation exists in the case of the cottontail papilloma established in domestic rabbits as described below. In virus tumors we are dealing with host-parasite relationships of considerable complexity, with most of the operative factors yet unknown. Nevertheless, at this time viruses seem to some investigators the most tangible factor as a general cause of both benign and malignant growths.

Researches on tumors are more than ever bringing up questions as to the nature of viruses. There has been a great tendency among those in the field of cancer research to regard a virus as a cell reproductive component gone wild. Such might be termed a feral gene. As yet, however, there is no significant evidence that viruses have their origin in host cells. Evidence presented by the data of this paper tends to establish that the infective agent of mammary carcinoma in mice is a parasite entirely foreign to normal mouse tissue. The origin of viruses from microbes and their nature as highly adapted parasites are reasonable concepts and correspond to the course of parasitism and the nature of highly adapted parasites as observed throughout the biological world.

Many tumors, both benign and malignant, that occur in various species of lower animals, birds and mammals, have been shown to be due to the presence of a filterable virus. The viruses causing the tumors generally are very specific and will reproduce the tumors only if inoculated into one species of animal and into one kind of tissue. The oral papilloma of dogs, for example, appears very specific for the dog and has not been successfully inoculated into other species nor into any tissue except oral epithelium. The papilloma of cottontail rabbits can be easily transmitted in series through cottontail rabbits. It can be transferred to domestic rabbits for one generation but cannot easily be maintained in them by serial inoculation. When the papilloma is inoculated from the cottontail rabbit into the domestic rabbit it often becomes cancerous. The papilloma virus cannot be isolated from the cancer, but cancer transplants can be transmitted in series in domestic rabbits by the use of living cancer cells as the inoculum. As the cancer transplant grows it appears to immunize the rabbit against the virus of the papilloma.[7]

Mammary cancer of mice has received a great deal of experimental study, and during the past five years has been the principal object of our investigations on virus tumors. Susceptibility to spontaneous mammary cancer in mice is a strong hereditary factor, and high- and low-cancer strains of mice have been developed by selective breeding. In a high-cancer strain, as many as 95 per cent of female mice may develop breast cancer after producing three or more litters. The development of this cancer of mice is greatly affected by hormones and nutritional factors. The cancer occurs in mice, however, only if a specific agent is present, as was first demonstrated by Bittner.[2] The agent is regularly transmitted from cancerous mothers to young mice through the milk and has been variously referred to as the milk influence, the milk factor, or the milk agent. Bittner[3,4] showed that the agent was filterable, and our co-operative studies[5] have demonstrated that the agent is of the magnitude of a virus. Injected into young mice of a susceptible strain, the agent will stimulate cancer-production after a period of seven months to a year. It is of the greatest importance that the agent has been found to be antigenic. Andervont and Bryan[1] prepared two antiserums from two rabbits and found that these serums neutralized the milk agent. In the antiserum groups he obtained only one tumor in thirty-six mice injected with a mixture of antiserum and milk agent, and ten in fifteen mice injected with the agent alone. We have extended this work with more controls and have established beyond question that the agent is antigenic. Upon injection of the agent into rabbits or rats, tumors do not develop but these animals are stimulated to produce antibodies. Our serums were prepared by immunizing groups of three or more rabbits by multiple injections of high-speed centrifugates of mouse tumor tissue. The centrifugal speeds were such as would concentrate particles of virus size. Antiserum from the immunized rats or rabbits neutralized the milk agent completely. The milk agent, therefore, has all of the cardinal characters of a filterable virus and may correctly be referred to as a tumor-producing virus.

Recently we have found that the mouse cancer antiserums not only neutralize the virus of mammary carcinoma[6] of mice but also inactivate the cancer cells[5] when they are suspended in the antiserum. Cancer cells are not inactivated by treatment with normal rabbit serum nor by treatment with serum from rabbits and rats immunized against normal mouse tissue. The cytotoxic property of the mouse cancer antiserum for cancer cells has been demonstrated in several experiments of which the following is an example.

A cancer cell suspension is prepared from masses of cancerous tissue removed sterilely from mice. The cancer tissue is forced through a tissue press. The macerated tissue is suspended in 0.9 per cent saline solution and placed in long test tubes to settle. After thirty minutes, the larger masses of cancer cells will have settled to the bottom and above will be a suspension of free tumor cells and small aggregates of tumor cells. If a susceptible mouse is injected with a small dose of these cells, a cancer will grow as a transplant tumor. In this experiment, ten mice were thus injected as a control group to assure the activity of untreated cells. For the actual test of cytotoxic activity of the serum, a portion of cancer cell suspension was mixed with five times the volume of mouse cancer antiserum and held for three hours at room temperature and for three hours at refrigerator temperature. Ten mice were then injected with 0.1 c.c. of the mixture. Two additional controls were set up by treating portions of the cancer cell suspension in a similar manner with normal rabbit serum and with serum from rabbits immunized with normal mouse tissue. The results are shown in Table I.

TABLE I. CYTOTOXIC PROPERTY OF MOUSE CANCER ANTISERUM

Rabbit antiserum—C3H tumor—ZBC mice without milk factor

No. mice	Materials injected	No. tumors 10 days	No. tumors 15 days	No. tumors 40 days	No. tumors 60 days
10	Tumor cell suspension + cancer antiserum	0	0	0	0
8*	Tumor cell suspension + normal mammary antiserum	1	3	8	8
10	Tumor cell suspension + normal rabbit serum	1	1	5	7
10	Tumor cell suspension + saline solution	10	10	10	10

*2 died from intercurrent infection.

From these results it is seen that the cancer antiserum prevented completely any tumorous growth of the cancer cells. The cancer cells suspended in saline solution grew rapidly to produce transplant cancers in all ten control mice. Most of the mice injected with cancer cells in normal mammary tissue antiserum and normal rabbit serum developed transplant cancers, but the cancerous growths appeared definitely later and were fewer in number. In this and other experiments it has been a consistent finding that normal rabbit and normal rat serums and the serums of rabbits immunized with normal tissues contain natural antibodies, or something of a similar nature, that affect cancer cells adversely and retard their growth to a limited degree. This effect, as found in normal tissue antiserum, is removed by absorption with normal mouse breast tissue cells but not with cancer cells. Thus, the slowing effect of normal tissue antiserum seems due to a nonspecific factor that combines better with normal cells than with cancer cells.

Absorption experiments with the mouse cancer antiserum reveal that the antibodies present are absorbed by cancer cells but not by normal breast tissue cells. This seems to establish the presence of antibodies that are specific for cancer cells and will not attack normal cells. The implication is that mouse cancer cells have taken on a new specificity and are immunologically different from normal mouse cells. It seems of considerable significance that our findings indicate that mouse cancer cells are antigenically different from normal cells and that the same antiserum will neutralize a virus and inactivate the cancer cells stimulated by that virus.

Originally thought to be more or less a character of protoplasmic disorganization transmitted genetically, the mouse cancer now clearly seems to be a virus infection with susceptibility and resistance strong genetic factors. With the addition of these findings on mammary carcinoma of mice to those previously established for other virus tumors, it would seem that we must more and more turn our eyes toward virus investigations in cancer research.

Discussion

DR. MAURICE B. VISSCHER, U. of M.: I am very much impressed by the newer work Dr. Green has been doing. It is now quite apparent that it is possible to produce antibodies against the milk influence. The part of Dr. Green's work that I had not known about until this evening is the demonstration that this antibody is effective not only in preventing the action of this virus-like agent in producing the carcinoma, but is also active in preventing the growth of carcinoma cells in cell suspensions. The two processes are quite different because in one case a carcinogenic agent is inhibited and in the other a complete cell is prevented from growing. To show that the actual carcinoma cell can be prevented from further growth by the action of an antibody of the sort produced in another species is really a most important step forward. I wouldn't suggest that one would necessarily find that this would have any bearing on the stopping of the growth of masses of cells but it is a step in that direction. I wonder if Dr. Green has anything to say about what masses of cells will do under comparable circumstances. He has given us an excellent presentation of very important new work.

The meeting adjourned.

J. A. LEPAK, *Secretary*

WOMAN'S AUXILIARY

Mrs. Edward V. Goltz, *President*
Saint Paul, Minnesota
Mrs. John K. Butler, *Editor*
Carlton, Minnesota

STATE BOARD

On January 30, Mrs. E. V. Goltz, president, presided at the winter meeting of the State Board of the Woman's Auxiliary of the State Medical Association, which was held at the Radisson Hotel at the University of Minnesota in Minneapolis. The guest speaker at the luncheon was Dr. Myron M. Weaver, Assistant Dean of Medicine, who outlined the latest developments of the Murray-Wagner-Dingell Bill and its implications. His talk was intensely interesting and informative.

BLUE EARTH COUNTY

The Blue Earth Auxiliary met at the Mankato Clinic on January 28. This was a business meeting only, and was devoted to a discussion of public relations and the cancer drive. Mrs. A. F. Kemp is county chairman of Cancer Control. On January 21, a joint meeting of the Blue Earth and Nicolett-Le Sueur program and executive committees was held at a luncheon at the Elks Cafe, Mankato. At this luncheon, a date was set for a public relations meeting at which Dr. Haddow M. Keith of the Mayo Clinic will be the speaker.

HENNEPIN COUNTY

On January 4 the Hennepin County Medical Auxiliary held a luncheon meeting at the Radisson Hotel. Mrs. Donald Bacon, wife of a Saint Paul physician, read the play *Dear Ruth.*

Mrs. N. H. Lufkin was chairman for the lunch and Mrs. Martin Nordland had charge of hospitality.

Mrs. Harold F. Wahlquist, a former president of Heneepin County Auxiliary, now national treasurer of the board of directors of the Women's Auxiliary of the American Medical Association, attended the mid-year meeting in Chicago.

The death of Dr. J. F. Curtin, husband of the president of the Auxiliary, saddened the members.

RAMSEY COUNTY

Miss Ruth Freeman, assistant professor of Public Health Nursing at the University of Minnesota, addressed the Ramsey County Auxiliary at the Ramsey County Library, January 28. Her subject was "New Developments in Public Health."

Mary Ellen Hoaglund, winner of the Junior award, and Beverly Hanklin, winner of the Senior award, of Saint Paul, read their essays on tuberculosis and were presented with war stamps.

ST. LOUIS COUNTY

On January 8, the St. Louis County Auxiliary met at the home of Mrs. Martin A. Wallace, Duluth. After the business meeting "Juvenile Delinquency" was the subject for discussion. On Saturday evening, January 26, Auxiliary members entertained their husbands at the annual dinner dance at the Kichi Gammi Club.

MOWER COUNTY

Mrs. L. G. Flannagan, of Austin, was hostess to her Auxiliary on January 28. Mrs. C. L. Sheedy of Austin gave the Program on Plans for Medical Care taken from *Hygeia.*

The Auxiliary, of which Mrs. C. C. Allen of Austin is president, is also active in its work on cancer dressings.

STEARNS-BENTON

Mrs. J. B. Gaida, president, was hostess to the Auxiliary at the Hays Hostess House on January 8. Miss Kay McEnroe, flight instructor of St. Cloud Airport, introduced by Mrs. H. B. Clark, talked on "What is New at St. Cloud Airport."

Stearns-Benton has lost two of its members. Mrs. C. S. Sutton, a former president, died January 7. Mrs. J. B. Beuing died January 28. Mrs. Henery Korda was introduced by Mrs. Carl Luckenmeyer, membership chairman as a new member. Mrs. Charles Donaldson and Mrs. Hayward Kaliher, Foley, were the out-of-town members present.

WASHINGTON COUNTY

Mrs. F. M. McCarten, Stillwater, was hostess to the Washington County Auxiliary on January 8. Mrs. R. Samson joined the Auxiliary as a new member.

WINONA COUNTY

The Winona Auxiliary met for dinner at Hotel Winona on January 7 and then adjourned to the home of Mrs. J. T. Benoit for the business meeting.

ACUTE ARTERIAL OCCLUSION

(Continued from Page 252)

Embolectomy and thrombectomy were not performed in any of these cases, and in only one instance was local anesthetization of the sympathetic ganglia necessary.

This is a small series of cases when compared with the series of McKechnie and Allen—but the results would indicate that use of the plan of treatment for acute arterial occlusion which we have recommended will result in saving some extremities and prolonging some lives. Except for the addition of anticoagulant therapy this plan of treatment is similar to that previously used on the vascular service for many years.

Effective
Convenient
Economical

THE effectiveness of Mercurochrome has been demonstrated by more than twenty years of extensive clinical use. For professional convenience Mercurochrome is supplied in four forms—Aqueous Solution in Applicator Bottles for the treatment of minor wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

Mercurochrome

(H. W. & D. brand of merbromin, dibromoxymercurifluorescein-sodium)

is economical because stock solutions may be dispensed quickly and at low cost. Stock solutions keep indefinitely.

Mercurochrome is antiseptic and relatively non-irritating and non-toxic in wounds.

Complete literature will be furnished on request.

In Memoriam

JOHN MILTON ARMSTRONG

In the passing on December 15, 1945, of John Milton Armstrong, the medical profession of Saint Paul lost a colorful member who had devoted much of his time and talent to the interests of the profession.

Born in Saint Paul, April 10, 1875, the son of George W. and Jane C. Armstrong, who came to Saint Paul in 1853, Dr. Armstrong graduated from Central High School in 1894. He obtained his medical degree from the University of Minnesota in 1901 where he was a member of Chi Psi and Nu Sigma Nu fraternities. After serving an internship at St. Joseph's Hospital in Saint Paul in 1901-2, he practiced for three months in Montgomery, Minnesota.

In 1902 he began practicing in Saint Paul and from 1907 to 1911 served as Assistant Commissioner of Health. Early interested in Dermatology and Genito-Urinary diseases, he was instructor in this department in the University of Minnesota medical school from 1903 to 1916. In 1913-14 he took postgraduate work in his specialty in Vienna, returning just prior to World War I. He was a fine diagnostician in his specialty.

Dr. Armstrong was a member of the Minnesota Academy of Medicine of which he was president in 1941, the Minnesota Dermatological Society, the Ramsey County Medical Society of which he was president in 1914, the Minnesota State and American medical associations.

He was greatly interested in medical literature and did more for the Ramsey County Medical Library to raise it to its present enviable status than any other individual. It was he who began and largely developed the library museum and obtained endowments in memory of former members for the purchase of rare volumes. He had served as a member of the library committee since 1906 and maintained his interest in the library even after his retirement from active practice in 1941. He worked particularly hard on the completion of files of old American medical periodicals and it is this collection especially that makes the library such an outstanding one. He contributed to the library many of his own books and many interesting items pertaining to very early Minnesota physicians, especially Saint Paul physicians.

Dr. Armstrong was business manager of the *Saint Paul Medical Journal* from 1908 until 1912 and was member of the Editing and Publishing Committee of MINNESOTA MEDICINE from 1924 until 1933. As a member of the original Historical Committee of the Minnesota State Medical Association appointed in 1928, he began the publication in 1938 of the History of Medicine in Minnesota in MINNESOTA MEDICINE and stimulated others to continue the work.

In January, 1932, he was elected to the Board of Trustees of the Hill Reference Library; in May, 1942, he was asked to serve as chairman of the library committee, and in 1943 he was elected chairman of this committee. Only the most severe illness kept him from fulfilling his committee duties and he attended the meetings until a few days before his death. Miss Starr, Librarian of the Hill library, calls him "a true bookman" and she says further: a "brilliant man, endowed as few are, he was modest. His suggestions were most helpful in building up the natural history collection of the library."

He was a charter member of the medico historical club *Kos Knidos,* and remained very active in this association which flourished in the Twin Cities until the beginning of World War II.

He was deeply interested in all branches of natural science which included every phase of natural history, astronomy and the microscopic study of fungi and parasites. He ground and constructed a very creditable reflecting telescope with which he and his friends studied the heavens. He was interested in the geological structure of the earth and had collected many specimens of fossils from the Ordovicion about Saint Paul. He possessed a beautiful collection of polished agates obtained from the local glacial drift. His interests led him into the study of ancient and modern archery and he accumulated an important, representative collection which he eventually presented to the Hill Reference Library. This gift occasioned an exhibition on Archery in this library. It was described by James Gray *(Saint Paul Dispatch,* February 19, 1943) as containing old, rare volumes (going back as far as the early 17th century), as well as scholarly, literary and technical items. James Gray labeled Dr. Armstrong "an unobtrusive, genial and humorous gentleman who has always loved the out-of-door life." His home-made bows and arrows made from various woods of North and South America were beautifully made. His intellectual curiosity led him to read and familiarize himself with the Einstein Theory of Relativity, when it first came out.

Books were his consuming interest. He was an omnivorous reader, with interest in all literature dealing with American medical history. In his search for material for the History of Medicine in Minnesota he literally went through hundreds of volumes of older American medical periodicals. His historical articles on the "History of Cholera in America" and "Dr. Purcell, the first Minnesota Physician," were very well received. His very interesting article on Dr. W. S. Cox (MINNESOTA MEDICINE, January, 1945) is proof of his gift of ferretting out information from every imaginable source. His wide reading in medical history is shown in one of his very early publications, "The Genesis of the Transmissible Disease" (1909), the prize essay of the Ramsey County Medical Society for 1908, which also shows his earnest application to his work in the Saint Paul Department of Health and his interest in bacteriology.

One of his finest qualities lay in his ability to stimulate similar interests in others. He enjoyed revealing the results of his searches. Being a storehouse of local, especially local medico-historical information, he was always ready to share it with those looking for it. With his varied hobbies he was a most colorful personality to all his friends and those who knew him well.

Dr. Armstrong married Ida Dobyns, of Shelbyville,

Stormy Weather

WHEN the menopausal storms set in—vasomotor disturbances, mental depression, unaccountable pain and tension—physicians today can take prompt, positive action to alleviate symptoms.

By the administration of a reliable solution of estrogenic substances, you may exert a gratifying measure of control.

For control of menopausal symptoms, you may turn with confidence to Solution of Estrogenic Substances, Smith-Dorsey . . . manufactured in the fully equipped, capably staffed Smith-Dorsey Laboratories . . . meeting rigid standards of purity and potency.

With such a medicinal, you can indeed *do something* about "stormy weather."

SOLUTION OF *Estrogenic Substances*

SMITH-DORSEY

Supplied in 1 cc. ampuls and 10 cc. ampul vials representing potencies of 5,000, 10,000 and 20,000 international units per cc.

WILLIAM JAMES COCHRANE

Dr. William J. Cochrane, for many years a resident of Lake City, passed away February 1, 1946, at the Lake City Hospital.

Dr. Cochrane was born in Lake City, Minnesota, June 27, 1867. He attended high school in Winona and received his M.D. from the College of Physicians and Surgeons in Chicago in 1895. He served as intern for eighteen months in the Illinois Eye and Ear Infirmary in Chicago, and then located at Quincy, Illinois, in 1896. He moved to Lake City in 1899.

He served as Captain in the Army Medical Corps during World War I and in 1920 and 1921 practiced in Iowa, returning to Lake City in 1921.

Dr. Cochrane was a member and past president of the Wabasha County Medical Society, and a member of the Minnesota State and American Medical Associations. He had been chairman of the Sanatorium Commission of Winona and Wabasha Counties since 1927, and had been president of the Lake City Hospital board. He also was local surgeon for the Chicago, Milwaukee, St. Paul & Pacific Railway. A Mason for fifty years, he was a Past Master of the local lodge.

In 1916 he took postgraduate work in eye, ear, nose and throat at the Illinois Post Graduate Hospital in Chicago.

Dr. Cochrane married Nellie A. Phelps of Lake City in 1901. He is survived by his widow and two daughters, Mrs. Leo F. McCaffrey of Brainerd and Mrs. John R. Wala of Beverly Hills, California, and one son, William, of Chicago.

Dr. Cochrane had been a member of the Congregational Church in Lake City since 1901 and had served as deacon and trustee. In 1943 he was elected president of the Lake City Bank and Trust Company. He was active in civic affairs and held the respect and admiration of all who knew him.

THE Rh FACTOR

(Continued from Page 249)

tor and paid very little attention to the changes in the brain.

It becomes perfectly obvious that any blood bank or clinical laboratory which maintains a list of blood donors should include in that list the names of Rh negative individuals who may volunteer as donors. Such donors should preferably be male, and if female, should not have been pregnant, unless the husband happens to be Rh negative. Prompt transfusion with Rh negative compatible blood may save a life, either a hemorrhaging patient or an erythroblastic baby.

◆ Of General Interest ◆

Dr. Paul C. Benton has re-opened his offices at Gibbon, after an absence of three and a half years in the Army Medical Corps.

* * *

Dr. Henry Roemer has returned home to Winona from thirty-nine months of service in the Navy and has resumed his practice at the Winona Clinic.

* * *

After three years in service as a flight surgeon, Dr. Lawrence Larson has resumed his practice in Minneapolis, with offices in the Medical Arts Building.

* * *

Dr. John J. Ederer, formerly of Mahnomen, Minnesota, has retired from practice because of ill health and is now residing in Minneapolis.

* * *

Dr. Russell O. Sather has assumed the duties of health officer at Crookston, replacing Dr. Lyle Brown, who is ill.

* * *

Dr. Robert Fuller Mears, Northfield, has purchased a site for the erection of a modern clinic building as soon as materials are available.

* * *

Dr. David H. Rolig has closed his offices at Howard Lake and moved with his family to Saint Paul, where he is associated in practice with Dr. Olaf Sohlberg.

* * *

Dr. Joseph F. Bicek, 1267 Lowry Medical Arts Building, Saint Paul, announces the limitation of his practice to obstetrics and gynecology.

* * *

Dr. J. Arnold Malmstrom and Dr. Edward N. Peterson of Virginia, attended the sectional meeting of the American College of Surgeons held in Minneapolis during the last week of January.

* * *

Dr. Robert P. Buckley was elected president of the Board of Directors of the Duluth Mental Hygiene Clinic at the annual meeting. Dr. Buckley was formerly associated with the hospital in Coleraine.

* * *

Drs. Raymond J. Josewski and Lloyd Taylor, Stillwater, represent the medical profession on the health committee for Washington County, which has been organized by the County Board of Commissioners.

* * *

Dr. Thomas Byrd Magath, of the Mayo Clinic, was elected president of the State Board of Health at the annual meeting of the Board held in Minneapolis on January 24.

* * *

Discharged from the Navy after thirty-five months of service as lieutenant commander, Dr. Harold M. Skaug has returned to Chatfield and has resumed his medical practice.

* * *

Dr. Oscar F. Mellby, president of the Oakland Park Sanatorium at Thief River Falls, was re-elected at the annual business meeting. Dr. Baldwin Borreson, superintendent of the sanatorium, is secretary ex officio.

* * *

Dr. William R. Jones was re-elected chief of staff of Eitel Hospital at the annual staff dinner held at the Minneapolis Club. Dr. Frank Hirschfield was made assistant chief of staff, and Dr. Harold Reif secretary.

* * *

Effective February 1, Dr. Howard G. Bosland terminated his practice at Verndale to become associated with Dr. Berton J. Branton at his clinic in Willmar. Dr. Bosland had been practicing in Verndale since October, 1932.

* * *

Dr. Anthony H. Field, who for the past year was stationed in England with the 109th General Hospital, has resumed his practice of medicine and surgery at Farmington. His offices are in the Sanford Hospital Building.

* * *

Dr. Clarence W. Walter, Saint Paul, has resumed practice at 1210 Lowry Medical Arts Building after serving as Lieutenant Commander in the Navy. He was stationed for two years in the Aleutian Islands and then at the Navy Hospital at Long Beach, California.

* * *

Dr. Emmet V. Kenefick has re-opened his offices for the practice of internal medicine at 710 Lowry Medical Arts Building, Saint Paul. A captain in the Air Force, Dr. Kenefick was stationed at Tinker Field, Oklahoma City, and at the Santa Ana Air Base in California.

* * *

Dr. John R. Kelly, who before his induction into the Army Medical Corps was practicing at Aitkin, Minnesota, has opened offices at Cold Spring. Dr. Kelly was in service for three and a half years with eighteen months of foreign duty. During this time he was stationed in Canada and Alaska.

* * *

Dr. Gaylord Anderson, former Director of Public Health at the University of Minnesota, was guest speaker at the midwinter meeting of the Minnesota Organization for Public Health Nursing held in Coffman Union. Dr. Anderson only recently returned from military service.

* * *

Colleagues and friends of Dr. L. J. Alger, of Grand Forks, North Dakota, will be interested in knowing that

Dr. Alger, on a recent trip to California, where he attended the Clinical Postgraduate Convention in Los Angeles, solved transportation difficulties by flying his own Stinson Voyager.

* * *

Dr. L. G. Culver, Saint Paul, has resumed practice in association with Dr. Carl L. Larsen and Dr. Merritt W. Wheeler, specializing in ophthalmopathy and Otolarynogology, following discharge from the Navy where he served aboard the *Ticonderoga* and the *Kenton* as Commander.

* * *

Dr. Balcome, son of the late Dr. F. E. Balcome, who practiced in Saint Paul for thirty years, served in the South Pacific. He is a graduate of Macalester College and the University of Minnesota Medical School, and had been practicing in Saint Paul for nine years prior to his enlistment.

* * *

Dr. Donald Dukelow, director of public health education in the Minnesota Department of Health for the past eight and a half years, has been appointed secretary of the health and medical care division of the Minneapolis Council of Social Agencies. Dr. Dukelow is also a member of Mayor Humphrey's health advisory committee which was recently organized in an effort to combat the sharp increase in communicable diseases in Minneapolis.

After an absence of more than three years in the military service, Dr. Manford B. Dahle has returned to Glenwood and re-opened his offices in the Glenwood Theater Building. Following a year in the South Pacific, Dr. Dahle was on duty for the remainder of his enlistment in this country.

* * *

Dr. Harvey O. Beek has resumed the practice of internal medicine in his offices in the Lowry Medical Arts Building, Saint Paul Dr. Beek entered service as a member of the University Hospital Unit No. 26, but later was made chief of medical service at the 45th General Hospital located in Bari, Italy, with rank of lieutenant colonel.

* * *

Dr. Albrecht E. Muller, who has been practicing in Saint Paul since his discharge from five years in military service, has purchased a home in North Saint Paul and will open offices there as soon as equipment can be obtained. Dr. Muller is a graduate of the University of Minnesota Medical School and interned at St. John's Hospital in Saint Paul.

* * *

Dr. Joseph P. Spano, who was discharged from military service last November, has returned to his practice in Minneapolis and has re-opened his offices at 328 East Hennepin Avenue. Dr. Spano went overseas with the 250th Staff Hospital in November, 1943, and served in

THE MARY E. POGUE SCHOOL

For Retarded or Exceptional Children

Children are grouped according to type and have their own separate departments. Separate buildings for girls and boys.

Large beautiful grounds. Five school rooms. Teachers are all college trained and have Teachers' Certificates.

Occupational Therapy. Speech Corrective Work.

The School is only 26 miles west of Chicago. All west highways out of Chicago pass through or near Wheaton.

Referring physicians may continue to supervise care and treatment of children placed in the School. You are invited to visit the School or send for catalogue.

England, France, Belgium, Germany, Bavaria and Austria. He entered service in June, 1942, and was stationed at Fort Leavenworth for the first year.

* * *

The chief topic of discussion at the Health Workshop, which was sponsored by farm and labor groups at their joint convention in Saint Paul during the first week of February, was a medical program suitable for the masses and its cost. Delegates from Wisconsin, Minnesota, and both Dakotas united in a demand for political action which would initiate improvement of health standards.

* * *

Dr. A. C. Hilding was elected chief of staff of St. Luke's Hospital in Duluth, at the annual dinner meeting of the medical staff. The other officers elected at this time were Dr. Arnold O. Swenson, vice chief of staff; Dr. Charles Miller Bagley, secretary; Dr. Frank J. Hirschboeck, chief of medicine; Dr. Gordon C. MacRae, chief of obstetrics; and Dr. Arden L. Abraham, chief of x-ray.

* * *

Dr. Lawren B. Nesset, who was released from military service in January of this year, is now associated in the practice of medicine and surgery with Dr. Burton C. Ford at the Marshall Clinic in Marshall, Minnesota.

Dr. Nesset, who comes from Canby, Minnesota, graduated from Luther College in Decorah, Iowa, and the University of Minnesota. He interned at General Hospital in Minneapolis, where he was also in residence for a year. Overseas duty took Dr. Lawren into Germany and Czechoslovakia.

* * *

Two members of the Mayo Clinic, Dr. Charles W. Mayo and Dr. Donald C. Balfour, have been signally honored by the Chilean government which has made them commanders in the *Order de Merito*. The presentation of the order—the highest attainable by the medical profession in Chile—was made by Dr. Alejandro Garreton, professor of internal medicine at the University of Chile in Santiago, while he was in Rochester to observe methods of postgraduate study and procedures in practice of internal medicine.

* * *

Dr. Frederick P. Arny and Dr. Milton M. Balcome, recently discharged from duty as flight surgeons in the Army, are now associated in practice in St. Anthony Park, with offices at 2315 Como Avenue.

Dr. Arny, who graduated from the University of Minnesota Medical School in 1935, entered practice at Princeton, Minnesota, where he remained until his induction into the Army seven years later. He is the son of Professor Arny, a member of the faculty of the University. Dr. Arny's area of duty was mainly confined to the ETO.

* * *

One of the first British physicians to take advantage of the resumption of the reciprocal fellowships between England and the University of Minnesota, which were discontinued during the war, is Dr. Richard Mayon-White, of Sussex, England, now studying in the Department of Pediatrics. of medicine in England, study in this country is essential for him, since children's diseases are not treated as a special branch of medicine in England. Dr. Mayon-White and five other English physicians were awarded fellowships by the Rockefeller Foundation.

* * *

Four members of the Mayo Clinic, Dr. Wallace E. Herrell, Dr. Charles W. Mayo, Dr. Donald C. Balfour and Dr. Waltman Walters, took part in the program at the sectional meeting of the American College of Surgeons held in Minneapolis in January.

Dr. Herrell discussed "Treatment of Surgical Infections by Chemical and Antibiotic Agents." Dr. Walters was a discussion leader on "Treatment of Open Wounds." Dr. Mayo took part in a panel discussion on pre- and postoperative supportive treatment, and Dr. Balfour was the moderator of a discussion and open forum on graduate training in surgery.

* * *

The annual George Chase Christian Lecture in the field of cancer research was delivered at the University of Minnesota by Dr. Leonell C. Strong, associate professor of anatomy, Yale University School of Medicine, on February 7, 1946. Dr. Strong's subject was "Mice, Men and Malignancy."

A pioneer in the use of inbred strains of mice for cancer research, Dr. Strong's first contribution to the study was the theory that failure in growth of grafts of tumor tissue is a consequence of inherited differences between the tissues of the host and the tumor cell, and depends on genetic differences in tissues.

The following appointments to the consultant staff of the Veteran's Hospital in Minneapolis have been approved by the Veterans Administration: Dr. Charles D. Creevy, senior consultant in urology; Dr. Thomas Kinsella, senior consultant in thoracic surgery; Dr. Carl W. Waldron, senior consultant in plastic surgery; Dr. Nathaniel H. Lufkin, senior consultant in pathology; Dr. Joseph W. Baird and Dr. Arthur W. Friend, consultants in anethesiology; Dr. William J. Norman, consultant in urology, and Dr. William Hollingshead, consultant in medicine; all of Minneapolis. Dr. Rodney Kendall, of Saint Paul, has been made consultant in dermatology.

* * *

Following the completion of his terminal leave on February 1, Major Thomas R. Dolan entered medical practice at Caledonia in association with Dr. Jacob J. Ahlfs.

Dr. Dolan, a former resident of Green, Iowa, is a graduate of Loras College, Dubuque, and the St. Louis University Medical School, St. Louis, Missouri. Beginning his internship in 1940, he was at the Charity Hospital in New Orleans for a year and a half. Of four and a half years in military service, Dr. Dolan spent thirty months as flight surgeon with the 13th Army Air Force Heavy Bombardment Squadron in the Pacific Theatre. During the latter part of his service, Dr. Dolan was engaged in research in aviation medical problems.

Dr. Hugh Monahan has returned to practice in association with his father, Dr. Robert H. Monahan, and Dr. Claire C. Craig at International Falls, after two and a half years in the Army Medical Corps.

Dr. Monahan, who was a member of the medical reserve, was called into active service in July, 1943. He was in residence for fifteen months at Fitzsimons General Hospital in Denver, as assistant chief of the eye, ear, nose and throat section. Later he went overseas with the 70th Infantry Division as battalion surgeon and was stationed in France and Germany. When the war ended he was assigned to the 280th Station Hospital in Germany and the 15th General Hospital at Udine, Italy. Dr. Monahan intends specializing in diseases of the eye, ear, nose and throat.

Announcement has been made of the election of Dr. Jay Arthur Myers, Minneapolis, as chairman of the editorial board and editor-in-chief of *Diseases of the Chest*, as successor to the late Dr. Ralph C. Matson.

Other members of the editorial board are: Dr. Andrew L. Banyai, Wauwatosa, Wisconsin; Dr. Charles M. Hendricks, El Paso, Texas; Dr. Champ H. Holmes, Atlanta, Georgia (inactive), and Dr. Richard Overholt, Brookline, Massachusetts.

Scientific manuscripts should be sent to Dr. Jay Arthur Myers, 111 Millard Hall, University of Minnesota, Minneapolis 14, Minnesota. All notices and miscellaneous items for publication in the journal should be sent to the Executive Offices, American College of Chest Surgeons, 500 North Dearborn Street, Chicago 10, Illinois.

Senior members of the Academy of Medicine and seven honorary members were guests of honor at the dinner meeting of the Academy held at the Minneapolis Club on January 23. The honorary members, all from the University of Minnesota, are Elexious T. Bell, professor of pathology; Harold S. Diehl, dean of medicine; Henry L. Ulrich, clinical dean of medicine; Benjamin J. Clawson, professor of pathology; George D. Head, clinical professor of medicine; and Richard E. Scammon, dean of medical science. The seventh member, Adolph M. Hanson, Faribault, associate professor of clinical medicine, was unable to attend, because of illness. Lieutenant Colonel Edward Evans, associate professor at the University of Minnesota Medical School and senior consultant in orthopedic surgery at the Veteran's Hospital, Minneapolis, was chairman of the meeting. Dr. Evans had just returned from four years' service in the Army.

* * *

Dr. Robert D. Estrem and Dr. J. D. Mouritsen, recently discharged from military service, have rejoined the Estrem Clinic at Fergus Falls.

Dr. Estrem, a captain in the Army Medical Corps, served sixteen of his twenty-two months in service overseas. He was in general surgery at the 90th General Hospital in England his first six months across. Then he was assigned to the Sixth Armored Division under General Patton at the beginning of the Battle of the Bulge. The following five months he was in front-line service n a forward-aid station with the 86th Cavalry Division on the march through France, Belgium, Luxembourg and Germany. He was awarded the Bronze Star for particularly meritorious service.

Dr. Mouritsen entered the Navy in September, 1942, and was discharged in December, 1945. A lieutenant commander, he served aboard the USS *Colorado* in the Pacific for twenty-six months. He was in action at Tarawa, Kwajalein, Eniwetok, Saipan, Guam, Tinian, Leyte, Mindoro, Luzon and Okinawa, and was in Tokyo Bay when the peace terms were signed.

* * *

Friends and neighbors—five hundred of them—disregarding a temperature of fifteen degrees below zero, gathered from miles around for a party held in the high school at Willow River in honor of Dr. William C. Ehmkes's sixty-eighth birthday. Features of the program were addresses by Dr. Thomas Moe, of Moose Lake, and Dr. Paul G. Boman, of the Duluth Clinic. A biographical sketch of Dr. Ehmke's life was read, and the doctor was presented with a purse of money in appreciation of his many years of devoted service.

Dr. Ehmke was born in Le Sueur County. He graduated from Hamline University and took his medical degree at the University of Minnesota. Following his internship, he was made company doctor for the Atwood Lumber Company's camps in Pine County. That was more than forty years ago. Finding the country and the people to his liking, he established a practice and has continued it ever since. The "good doc," as he is affectionately known throughout the community, has not only ministered to the health needs of its people, but has also taken an active interest in civic affairs.

The Hennepin County Medical Society has announced the return from service of the following members:

Dr. Lyman B. Clay has resumed his practice at 2703 East Lake Street. Dr. Clay was a lieutenant commander in the Navy with duty in the South Pacific.

Dr. Harold F. Buchstein, neurological surgeon, had served in naval hospitals at Great Lakes, Illinois, Corona, California, in the South Pacific and on Okinawa, since January, 1942. His offices are in the Medical Arts Building.

Dr. Meyer C. Goldner, orthopedist, has returned to his offices in the Medical Arts Building. He was a staff member of General Hospital 26 in North Africa, and was chief of orthopedics with the group for some time.

Dr. O. L. Norman Nelson, internal medicine specialist, had been in the Navy since October, 1942, as a lieutenant commander. His offices are in the Medical Arts Building.

Dr. Everett C. Perlman, pediatrician, has reopened offices in the Medical Arts Building. A lieutenant colonel in the Army, Dr. Perlman was in service from March, 1941.

Dr. Robert O. Quello has returned to general practice at 4103 Chicago Avenue. He was in service for three years and was stationed at the Army flying school in Waco, Texas, and Pampa, Texas.

Dr. Theodore L. Stebbins, served in the Army at Fitzsimons General Hospital, Denver, Colorado, and Gen-

eral Hospitals 188 and 156 in England. Dr. Stebbins is an urologist, with offices at 1409 Willow Street.

Dr. John D. Galloway, orthopedist, a major in the Army, was with General Hospital 26 in England, North Africa and Italy. He has re-opened his office in the La Salle Building.

Dr. Raymond P. Hawkinson has returned to general practice at 1025 Broadway. Dr. Hawkinson, with the rank of major, was executive officer at Hoff General Hospital, Santa Barbara, California.

Dr. Maynard C. Nelson, surgeon, a lieutenant commander in the Navy, served in the Pacific Theatre for twenty-two months, and as chief medical officer of Navy V5 at the University of Minnesota. His offices are at 421 Medical Arts Building.

Dr. Lewis J. Roberts has resumed general practice in his offices at 3827 Central Avenue in association with Dr. Hoff D. Good. A lieutenant commander in the Navy, he served twenty months with Naval Aviation in Hawaii.

Dr. Stanley W. Roberts has resumed practice in his offices at 1110 Lowry Avenue. Dr. Roberts, a lieutenant commander in the Navy, served a year with the amphibious forces in the Southwest Pacific. Later he was in the office of Naval Officer Procurement.

Dr. Arthur N. Russeth has re-opened his offices at 302 Physicians and Surgeons Building. A lieutenant commander in the Navy, Dr. Russeth was in the South Pacific with the Marines for twenty months. Later he was at the Minneapolis Naval Air Station and the Naval Hospital at Corvallis, Oregon.

Dr. Donald B. Simonson has resumed his practice at 4151 Thomas Avenue North. Dr. Simonson, a captain in the Army, served with a hospital train in France and Germany, and later at the Torney General Hospital at Palm Springs, California.

* * *

Dr. Burton Rosenholtz has returned to his pediatric practice with offices at 814 Lowry Medical Arts Building, Saint Paul, following discharge from the Navy. He served as Lieutenant Commander in the Far Pacific, much of the time caring for shock casualties aboard an Ambulance Hospital ship.

UNIVERSITY NEWS

The Board of Regents of the University of Minnesota has announced the appointment of Dr. Donald Wilson Hastings as professor and head of the Department of Neuropsychiatry in the Medical School. Dr. Hastings is replacing Dr. J. Charnley McKinley, who has resigned because of ill health.

Since his release from the Army in August, 1945, where he had served as chief psychiatrist of the Eighth Air Force in England, and later as chief Air Force Psychiatrist in Washington, Dr. Hastings has been professor of psychiatry at the Women's Medical College in Philadelphia. He is a graduate of the University of Wisconsin Medical School and interned at the Philadelphia General Hospital. He held a Rockefeller Fellowship in Psychiatry at the Pennsylvania Hospital and Institute for Nervous and Mental Diseases in 1936-38. From 1938 to 1939 he was psychiatrist at the Student's Health Service at Harvard University. Appointed clinical director of the Pennsylvania Hospital in 1939, Dr. Hastings remained there until his induction into military service. During this same period he was also instructor in psychiatry at Jefferson Medical College. He assumed his duties at the University of Minnesota on March 16.

* * *

Dean Harold S. Diehl announces the appointment of Dr. Robert A. Aldrich and Dr. Clifford G. Grulee, Jr., to special teaching assistantships in Pediatrics, and Dr. Charles U. Culmer to a similar post in Surgery. Dr. Aldrich holds the Bachelor of Arts degree from Amherst College and the Doctor of Medicine degree from Northwestern University Medical School. Dr. Grulee holds the Bachelor of Arts degree from Wayne University and the Doctor of Medicine degree from Northwestern University Medical School. Dr. Culmer holds the Doctor of Medicine and the Doctor of Philosophy degrees from Northwestern University. The funds for the support of these special assistantships have been provided by the Rockefeller Foundation as part of its program to aid in the development of selected young men whose preparation for teaching and research posts was interrupted by military service. Additional appointments are under consideration in Surgery, in Neuropsychiatry, and in Preventive Medicine and Public Health.

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

Dr. Joel C. Hultkrans

2527 2nd Ave. S., Minneapolis, Phone At. 7369

FACIAL INJURIES

(Continued from Page 239)

it aids in the acts of swallowing and coughing. The hemoglobin should be brought rapidly to normal by means of repeated transfusions in all cases in which the viability of important bone fragments or of large soft tissue flaps is in question. Oxygen can be administered through a nasal catheter or tracheotomy tube during the first postoperative days for the same reason. Even in severe facial injuries the patients should be out of bed for intervals on the first or second postoperative day if possible. Every effort should be made to prevent stasis and atelectasis. The postoperative use of penicillin and sulfadiazine undoubtedly helps prevent pulmonary complications.

When the jaws are immobilized a liquid diet becomes necessary. A high caloric liquid diet with supplemental vitamins is given. It is well to chart the patient's weight so that any undue loss can be noted. As a general rule, the patients lose weight the first week and thereafter maintain that weight or gain to their previous level.

Severe facial injuries are a psychiatric as well as a surgical problem. Since the patients are made ambulant as early as possible they are encouraged to circulate about the wards. They must not be allowed to develop seclusive trends.

CANCER DETECTION CENTERS

(Continued from Page 269)

feasible, clinics financed and aided by the Minnesota Cancer Society, will be extended to other communities as initiation, organization, and approval by the County Medical Societies is forthcoming. The Committee wishes to make it clear that at any time a group of physicians decides to establish a clinic, without the financial help of the Minnesota Cancer Society, it is perfectly free to do so provided it has the approval of the local County Society.

An interesting observation was the experience noted in Philadelphia[6] where over 70 per cent of the 2,552 patients examined in one year in the detection clinics were referred to their family physicians for some physical defect or other, not necessarily neoplastic in nature. Some of these clinics were originally established on the basis of one evening clinic a week, and grew with experience and demand. The experience of cancer detection clinics in Chicago[7], Milwaukee[2], New York[3], Philadelphia[4], and Los Angeles[5], testify to the value of periodic examinations of apparently healthy adults for cancer or its precursors.

The rooster's legs are straight.

The boy's are not.

The rooster got plenty of vitamin D.

Fortunately, extreme cases of rickets such as the one above illustrated are comparatively rare nowadays, due to the widespread prophylactic use of vitamin D recommended by the medical profession.

One of the surest and easiest means of routinely administering vitamin D (and vitamin A) to children is MEAD'S OLEUM PERCOMORPHUM WITH OTHER FISH-LIVER OILS AND VIOSTEROL. Supplied in 10-c.c. and 50-c.c. bottles. Also supplied in bottles of 50 and 250 capsules. Council Accepted. All Mead Products Are Council Accepted. Mead Johnson & Company, Evansville 21, Ind., U.S.A.

GOOD POSTURE IS A GOOD HABIT
BAD POSTURE
GOOD POSTURE
THE PELVIS IS THE KEYSTONE OF POSTURE
IMPROVED POSTURE IMPROVES APPEARANCE
GOOD BODY MECHANICS AIDS PHYSICAL EFFICIENCY

FULL COLOR HUMAN INTEREST GOOD POSTURE CHART expressly designed for physicians' offices, clinics and health centers. One of four in the new 1946 group added to the standard series widely distributed in schools, colleges, industrial plants, "Y's" and similar outlets. Write for your office copy of this educational chart on your professional letterhead. Samuel Higby Camp Institute for Better Posture, Empire State Building, New York 1, N. Y.

May 6 to 11 CAMP *8th Annual*
NATIONAL POSTURE WEEK

Once again National Posture Week takes its place on the calendar of public health education as it dramatizes the sound and ethical year-round program focusing the attention of the country on the significance of good posture as one element in good health and physical fitness.

Since no field is more subject to the dangers of "glamorizing" and lay "experting," the Institute in all its appeals stresses the necessity of "seeing your physician" as the first step in the improvement of poor body mechanics. Distribution of authentic literature through schools, colleges, medical and government bodies; and industrial, professional and civic public health groups is an important part of the program. Press and radio give serious coverage.

We hope to merit the continued cooperation of the medical profession during the first post-war observance of National Posture Week as peace presents its varied problems to those charged with maintaining the health of the nation.

a new liquid dosage form

ACCEPTED AMERICAN MEDICAL ASSN.

Available in 6 fl. oz. bottles

Benzedrine Sulfate — formerly supplied
in tablet form only — is now available also as:

BENZEDRINE SULFATE ELIXIR

Benzedrine Sulfate Elixir, N.N.R.—highly palatable, pleasant in appearance and easily tolerated — is identical in action with Benzedrine Sulfate Tablets. It is a preferred form of administration for invalids, convalescents, children and the aged. This new preparation contains Benzedrine Sulfate (racemic amphetamine sulfate, S.K.F.), 2.5 mg. per 5 cc. (1 teaspoonful); and has the same pharmaceutical properties as low-alcoholic, mildly acidic elixirs.

NOTE: When you next write for Benzedrine Sulfate, please remember to specify which of the two dosage forms you wish to prescribe — 'Tablets' or 'Elixir'.

Most
DEPENDABLE
Method

The combined use of an occlusive diaphragm and vaginal jelly remains, in the published opinions of competent clinicians, the most dependable method of conception control.

Dickinson[1] has long held that the use of jellies alone cannot be relied upon for complete protection. It is noteworthy that in the series of patients studied by Eastman and Scott[2], an occlusive diaphragm was employed in conjunction with a spermicidal jelly for effective results. Warner[3], in a carefully controlled study of 500 patients, emphasized the value of a diaphragm.

In view of the preponderant clinical evidence in its favor, we suggest that physicians will afford their patients a high degree of protection by prescribing the diaphragm and jelly technique.

You assure quality when you specify a product bearing the "RAMSES"* trademark.

CHOLECYSTECTOMY: ITS ORIGIN AND PRESENT STATUS

JUSTUS OHAGE, M.D.
Saint Paul, Minnesota

THIS year, 1946, marks the sixtieth anniversary of the first—and incidentally successful—cholecystectomy performed in the United States. The operation was done in this city, Saint Paul, Minnesota, at St. Joseph's Hospital.[8,11] The date was September 24, 1886. I admit to a special interest in this operation and to the origins of cholecystectomy because the operator on this occasion was my father, Justus Ohage, assisted by Drs. Nelson, Schulin, Dedolph, Denny and Welsh, also of this city.

This year also marks the hundredth anniversary of the birth of the surgeon who performed the very first cholecystectomy.

Today cholecystectomy is a common — one might almost say routine—operation. It has been performed many thousands of times both in this country and abroad. Yet a little more than sixty years ago it was a question whether it could or should be done at all. It is interesting also to note that cholecystectomy has been a fairly stable operation. Except for general improvements in operative technique, especially with regard to asepsis, we are doing it today in much the same fashion that it was done by European and American surgeons who first attempted it.

I shall take this occasion, therefore, to recall for contemporary as well as historical interest the origins of cholecystectomy. While I do not pretend in any sense to be a historian of medicine, I am persuaded to the practical and useful aspects of medical history. The editors of the newly organized *Journal of the History of Medicine and Allied Sciences* have written aptly in an introductory editorial:[10]

> "The historical approach is invaluable in comprehending the nature of difficult problems. We must have a knowledge not only of the actions of the past, but of the mental struggles, the philosophical conflicts that preceded action."

From that approach I wish to review in some detail the early classical contributions to cholecystectomy and its forerunner, cholecystotomy.

Credit for performing the first successful removal of the gall bladder[4] goes to the surgeon Carl Johann August Langenbuch[6], the hundredth anniversary of whose birth occurs this year. Langenbuch was born in Kiel, Germany, in 1846. After graduation from the University of Kiel in 1869, he went to Berlin, where he began his career as an assistant in the Bethany Hospital. From 1873, until his death in 1901, he was an important figure at the Lazarus Hospital. He was a zealous worker in several fields and published much. To his name is attached the research which eventuated in nerve-stretching procedures in tabes. He also worked extensively in the study of diseases of the liver and gall bladder; his "Surgery of the Liver and Gall Bladder" was published in 1894. He was among the first who dared to resect a lobe of the liver. He dealt also with hydatids of the liver and the treatment of seriously exposed large blood vessels with zinc chloride paste. But we remember Langenbuch tonight as the first surgeon who successfully extirpated the gall bladder.

I quote now from Langenbuch's discussion and

Presidential Address before the Ramsey County Medical Society, Saint Paul, Minnesota, January 28, 1946.

description of this first successful case. This paper, in German, appeared in the *Berliner Klinische Wochenschrift* in 1882 under the title: "A Case of Extirpation of the Gall Bladder in the Treatment of Chronic Gallstones: Recovery."[6] In passages that reflect the "mental struggles, the philosophic conflicts that precede action," Langenbuch writes:

> "The surgery of the gall bladder is still in the infancy of its development, but it does exist and the names of Petit, Thudichum, M. Sims, Kocher, G. Brown, Lawson Tait, König and others are in a general way associated with it. Concerned with stone formation, they have until now gone only so far as exposing the gall bladder freely and have been satisfied to widen fistulas and extract stones whenever hydrops or empyema of the gall bladder call for an operation. . . . They have busied themselves with the product of the disease, not the disease itself."

Langenbuch himself first became seriously interested in the problem in 1874 when he encountered a particular case of a forty-year-old man with insidious gallstones. He was prompted to undertake a series of animal experiments which brought him to the conclusion that:

> "Of all abdominal operations to which laparotomy is the prelude, extirpation of the gall bladder with preliminary ligature of the cystic duct appears among the least hazardous to attempt."

In June, 1882, shortly after the conclusion of his experiments, Langenbuch was called into consultation by Dr. N. Meyer to see a forty-three-year-old patient, Mr. D., a magistrate secretary in Berlin, who was suffering from acute gallstone disease. Langenbuch reports his history thus:

> "He had endured his first mild attack in 1866, but recovered. Thereafter attacks came more frequently and jaundice increased. He had taken the cure at Carlsbad for three years without success. The first year he had weighed 89.5 kilograms, the next year 75 kilograms and now only 52.5 kilograms (126½ pounds). For the last nine months the recurrent pain was so intense that he had to be maintained on increasing doses of morphine. He was very depressed, he constantly complained, his strength was failing and without morphine he could not leave the house. He had to give up his employment and his future indeed looked black."

Langenbuch explained the risk and the possibilities of the projected operation, cholecystectomy, to the patient. On July 10, 1882, the patient entered the Lazarus Hospital and asked Langenbuch to undertake the operation. The patient was kept in bed for five days, during which time he suffered two acute exacerbations of pain.

The operation was scheduled for July 15, 1882, and did indeed take place on that day. "As demanded by the novelty of the case," writes Langenbuch, "preparations were made for carrying out the operation with all aseptic precautions." At this point we may recall that the modern era of surgery, introduced largely by Joseph Lister, was still very young and the distinction was not altogether clear between antiseptic surgery, employing carbolic acid dressings and spray, and aseptic surgery, emphasizing the exclusion of contaminating agents by the practice of absolute cleanliness. Lister's famous paper "On the Antiseptic Principle of the Practice of Surgery" had appeared only fifteen years previously, in 1867.

With aseptic precautions as they were understood in 1882, then, and with the assistance of Dr. A. Martin and Prof. Dr. F. Busch as well as the presence of other guests, Langenbuch began the first successful cholecystectomy. He has described the operation and its results as follows:

> "The operation proceeded smoothly, through a T incision. The gall bladder was found to be massively full of gall and was emptied by aspiration with a syringe. Two chestnut size cholesterin gallstones were found. When the gall bladder was detached from the liver, a small venous bleeding occurred. This was controlled with a catgut stitch. . . .
>
> "After the operation the patient felt no pain and slept well the following night. Next day his pulse and temperature were normal; he felt no pain and he smoked a cigar. He left his bed on July 27. His old pain had not recurred up to mid-November. He had gained 13 kilograms in weight and he no longer needed morphine."

At this time Langenbuch felt that he had answered the physiologic and technical questions concerning the feasibility of cholecystectomy in man. He wrote: "Clinically I believe we should be alert to extirpation of the gall bladder, with preliminary ligation of the cystic duct, as the least dangerous and most hopeful method for the relief of many pathological processes arising in these organs." Experience has justified his statement.

Within four years after Langenbuch's first cholecystectomy, the operation was performed nine times, with eight recoveries, a mortality rate of 11 per cent.[9] The operation in this city, the first in the United States, was the ninth in the world. Five were performed by Prof. Langenbuch, with one death, two by M. Thiriar, both successfully, one, successfully, by Courvoisier.

Obviously, however, cholecystectomy was not the only surgical procedure entertained for relief of diseases of the gall bladder. Its immediate prodecessor was cholecystotomy. Credit for the first cholecystotomy for the removal of gallstones[4] has been assigned to an American physician, John Stough Bobb[2] (1809-1870), who reported a case of lithotomy of the gall bladder in the Transactions of the Medical Society of Indiana for 1868. The operation of lithotomy for the removal of gallstones had been proposed in the 18th century by the French surgeon, Jean Louis Petit[1] (1674-1750), who lectured on surgery at Paris and devised many operations. He suggested that if the gall bladder was dilated and adherent to the abdominal wall, it might be punctured and stones extracted with a long forceps. Similarly, fistula might be dilated for this purpose. Vogel, a surgeon of Lübeck, is said to have performed this operation in the 18th century and considered it one of "the very finest surgical operations." Borrichus[12], in the 17th century, observing many fatal cases of "dropsy of the gall bladder" from impacted gallstones, had among others raised the question of surgical interference. Far earlier, in antiquity, Hippocrates and Galen gave descriptions of gallstones and diseases dependent on them.

However, the classical description of cholecystotomy and in fact the invention of this name for the operation itself is ascribed to James Marion Sims. Sims was an American, born in 1813 in South Carolina. He practiced in Alabama and New York. Sims was one of the early presidents of the American Medical Association (1876). He later moved to Europe where he was made an honorary fellow of the obstetrical societies of London, Dublin and Berlin. He died in 1883. His classical "Remarks on Cholecystotomy in Dropsy of the Gall Bladder"[12] were published in the *British Medical Journal* in 1878.

In this paper Sims reports the case of an American woman, aged forty-five, a resident of Paris, on whom he performed the operation of cholecystotomy. The date was April 18, 1878. This patient had all the symptoms of acute mechanical obstruction of the gall bladder. She is described as being mahogany colored with jaundice. "The benefit of the operation," Sims reported, "was shown by immediate relief of pain, itching, nausea, vomiting and in the production of stools natural in color and odor." Unfortunately, however, the patient died eight days after the operation, due to hemorrhage. Sims considered the operation nevertheless a "triumph for Listerism, for postmortem examination proved that there was not the least trace of peritonitis or other untoward complication to be found as a direct result of the operation."

In the course of the operation, under ether anesthesia, Sims amputated a portion of the gall bladder protruding through the incision. Apparently it did not occur to Sims to remove the entire gall bladder. Lacking Langenbuch's extensive studies he may have been extremely doubtful whether life was compatible with the absence of the gall bladder. At any rate he states: "It will be better to incise the gall bladder rather than to remove any portion of it."

I quote now a few pertinent statements from Sim's paper, again illustrating the "mental struggles, the philosophical conflicts that precede action" in the direction of gall-bladder surgery. Sims wrote:

> "I believe the operation is unique. Is it justifiable? I think it is because it is an imitation of the process adopted by nature in all cases in which recovery takes place. Death is absolutely certain in every case where the gall ducts are mechanically obstructed unless an outlet be obtained either into the alimentary canal or by a fistulous opening externally through the abdominal wall. . . . But this case proves that it is not necessary to wait for the tedious efforts of nature. . . . Were I called on to operate again under similar circumstances I would not procrastinate it a day after the diagnosis was fully established. For it is certain that the longer it is put off, the more the blood becomes poisoned by the bile and the more the chances of recovery are diminished."

"It is too much the fashion, nowadays," wrote Sims in 1878, when Listerism was making possible operations that would have been considered absurd a few years previously, "to coin new names for old operations. But this is a new operation and we must find a name for it. Cholecystotomy (from the Greek, "gall," "bladder" and "incision") will answer." He rightly predicted that cholecystotomy would "open a great new field in the domain of abdominal surgery."

The first successful case of cholecystotomy with recovery, five weeks after operation, was performed by Kocher[5] in June, 1878.

Experience over more than sixty years has now demonstrated that cholecystectomy as introduced by Langenbuch rather than cholecystotomy devised by Sims is the more useful and probably the less hazardous operation, though each has its place. Very recent statistical studies appear to bear this out. In a series of 332 cases of acute cholecystitis reviewed by B. C. Smith[13] in 1945, cholecystectomy was performed on 223 patients with a mortality rate of 3.5 per cent, and cholecystotomy was performed on 103 patients with a mortality rate of 11.6 per cent. In another series of 123 cases of acute cholecystitis reviewed in 1945 to determine the comparative value of early (that is, within seventy-two hours) and late operative intervention, McGuigan[7] concludes that when delay results in improvement of the condition of the patient, cholecystectomy is to be preferred to cholecystotomy and seems to be better borne than the less radical operation. The average mortality in this series was 12.7 per cent for the early operations; 2.38 per cent for the delayed operations.

In 1946, then, the year marking the sixtieth anniversary of the performance of the first cholecystectomy in the United States and the hundredth anniversary of the birth of the surgeon who first performed this operation, we need conclude nothing more elaborate than to offer affirmative testimony that the earliest hopes as to the utility of this operation have been amply confirmed. Would that all surgical hopes were as fully justified.

SOCIALIZE EVERYTHING OR NOTHING

On all sides one hears: Why does the medical profession oppose socialized medicine? Not all of the profession does. Those who do oppose it do so because they think, with good reason, that it will not work as well as the present system of practice *unless everything else and everybody else is "socialized" also.* Their good reason is the way it has failed to work well in countries where it has been tried.

There seems little cause to "socialize" medicine and to stop there. Free medicine is now working well, advancing, making progress, as everyone knows, in a free economy. Should we "socialize" medicine and not the patients? Should we "socialize" medicine and not the manufacturers who make the drugs, the appliances, the automobiles, the surgical instruments, the biologic products which medicine uses? And how about the labor unions whose members make the things that doctors need? Shall they be "socialized" also?

If this country is heading toward conversion to a socialist republic, we had better know about it. If it is true, as Lincoln said, that we cannot exist half slave, half free, it seems absurd to think we can exist half socialized, half free, no matter who says so. We paid the price of a civil war to settle the first question—what price this one? An answer to this seems called for.

In homely phrase, it's "whole hog or none." Medicine is only a tiny, if nubbly, minority of the electorate, probably not really worth the trouble to socialize—except as an experiment, a trial balloon so to speak. If it can be "socialized," if the acceptable political and other technics can be thus worked out as, for instance, they were in the "laboratory war" in Spain, then the other professions, as well as business and manufacture, can be subsequently "blitzed." Underneath the double talk lies the single objective.

Well, if it is to be that way, maybe we had better think about it. Things like the Wagner bills, the Pepper bill, E.M.I.C., are handy tools to toss into the machinery of a free economy. Perhaps nobody but the doctors will object to them—until it is too late. Seen against the background of the recent elections in Britain, the rising tide of socialist influence in Europe, the growing dominance of labor in American politics, it is not surprising that attempts should be made, under whatever guise, to convert this country to a socialist republic. Technics of boring from within established political parties are well known. Confusion in the popular mind between socialism, communism, democracy and republicanism has been worse confounded by attempts to explain their differences.

The first great American dependency was created following the panic of 1929. People learned to look to ever-loving government for their very existence in many cases. The myriad alphabetic agencies spring up with sprightly benevolence during the liberation period of Congress to assume the guardianship of the individual rights and privileges of the taxpayer-citizen in a difficult era, to be later superseded by the regulatory governmental mechanisms of the war years. Crisis followed serried crisis for some reason, lurid interagency civil war filled the citizen with respect for constituted authority as soon as he recovered from his nausea.

Now it is proposed to lure the voting taxpayer into forgetfulness by giving him ever-loving government medicine, "socialized" medicine. You don't believe it? Well, look at H.R. 3293 or S. 1050. Don't bother your congressman or senator to send you a copy of the bills. Don't you know there's a—peace on? Everything is lovely now.—Editorial, *New York State Journal of Medicine*, 45:2401, (Nov. 15) 1945.

ACUTE LESIONS OF THE ABDOMEN

Diagnosis and Treatment

ARNOLD S. JACKSON, M.D., F.A.C.S.
Madison, Wisconsin

WHEN attempting to establish a diagnosis in the case of a patient complaining of acute abdominal distress, one must consider many possible medical as well as surgical conditions.

Frequently the signs and symptoms are sufficiently clear to enable one to arrive quickly at a correct diagnosis. If the case is not typical, then by the process of elimination, by the assistance of laboratory tests, and by a careful study of the findings the nature of the disease may be determined. Often the problem is not solved until an exploratory operation has been performed, and then the pre-operative diagnosis may be proved incorrect.

Certain medical conditions may closely mimic surgical diseases of the abdomen, and one must guard against confusing the two. In children especially such diseases as acute pyelitis and pneumonia are apt to simulate appendicitis. A careful study of the lungs in an early case of pneumonia may fail to reveal any characteristic findings, and the child may only complain of abdominal pain. Elevation of the temperature and leukocyte count occur in both. There may be abdominal tenderness but seldom rigidity in pneumonia. The accessory muscles of respiration in the nose may be activated in acute pulmonary lesions. Repeated studies of the urine may show pus and, along with a high fever and chill, point to pyelitis.

Several months ago I performed a cholecystectomy on a woman thirty-eight years of age who had been under treatment for coronary disease for a considerable time. She had suffered repeated attacks of severe substernal pain radiating to the right arm. Electrocardiograph studies made by the patient's physician during and shortly after the attacks had apparently confirmed the diagnosis of coronary disease. It is a well-known fact, however, that acute biliary attacks may alter the electrocardiographic tracing so as to give the picture of coronary disease. Cholecystectomy was performed, a large number of stones were removed, and the patient entirely relieved of pain. To further confuse the problem, cholecystitis conditions and coronary disease are occasionally associated.

Acute enteritis, commonly termed "intestinal flu," may so closely resemble acute appendicitis that it is impossible to establish a correct diagnosis without resorting to surgery. In a few instances an acute gangrenous appendix develops within twenty-four hours or less from the time of onset of an attack of acute enteritis. In children one may be greatly concerned as to the advisability of operation in certain of these cases. The past year there has been a very high incidence of acute enteritis, and still there is no solution as to its etiology. Years ago it seemed to occur in mild epidemic form during the summer months; more recently it appears to have no seasonal incidence.

Numerous other medical conditions, such as acute lead colic, tabetic crises, acute ruptured Graafian follicle, allergic disturbances, and gastrointestinal hemorrhage, may occasionally puzzle the diagnostician.

Among the more common surgical diseases there are: appendicitis, cholecystitis, pancreatitis, mesenteric thrombosis, perforated ulcer, traumatic lesions, intestinal obstruction (including volvulus, intussusception, strangulated hernia and neoplasms), torsions of the omentum, regional enteritis, and congenital anomalies. Then, too, acute lesions of the pelvis, such as ruptured tubal pregnancy, strangulated and ruptured ovarian cysts, acute salpingitis and rupture of the uterus must be considered. Likewise a number of lesions of the genito-urinary tract, as renal and ureteral calculi and pyelitis, may confuse the examiner.

Acute Perforated Ulcer

The appearance of the patient may afford some help in arriving at a correct diagnosis. In the case of an acute perforated ulcer, he may sit up in bed with his knees drawn up, finding it too painful to lie down. He may be suffering severe pain, requiring morphine for relief. This, of course, should not be given until the diagnosis is fairly definitely determined. He may give a history of an ulcer with a sudden onset of a gun-

---

Expansion of address before the Saint Paul Surgical Society, January 17, 1945.

shot type of pain following some dietary indiscretion such as drinking beer on an empty stomach. The development of a boardlike rigidity of the abdomen within an hour or two of the onset and the finding of a gas bubble under the diaphragm by x-ray confirm the diagnosis and call for immediate operation.

The abdomen is opened preferably under spinal anesthesia. The perforation is located and closed by three or more interrupted chromic sutures and covered by an omental tag, if possible, and 10 Gm. of sulfathiazole in saline is left in the peritoneal cavity after its soiled contents have been aspirated. I have been closing the abdomen without drainage in patients operated upon within twelve hours of perforation. Duodenal suction and intravenous glucose and saline are used as indicated.

Acute Pancreatitis

Acute pancreatitis is fortunately of rare occurrence as it is usually fatal. Its onset is characterized by a severe upper abdominal pain, shock, prostration, high fever, and high leukocyte count. Surgery has never proved very successful.

On opening the abdomen in a recent case, we found the typical condition of acute pancreatitis with free fat in the peritoneal cavity and a huge hemorrhagic pancreas. We followed the accepted procedure of placing drains to the pancreas, but the case terminated in the usual manner, despite penicillin and sulfonamide therapy. Some internists advocate medical treatment of acute pancreatitis after a diagnosis has been established by the amylose test.

Acute Cholecystitis

Two schools of thought have existed among the surgeons of this country regarding the treatment of acute cholecystitis. Some advocate immediate operation, and others favor a more conservative treatment and delayed operation. It is my belief that no set rule can be used but that each case must be treated according to the duration, severity, and progress of the disease. If the toxemia is subsiding, I prefer to wait a few days and then operate. If the fever and leukocyte count are rising, indicating the development of empyema, delay in operating may only lead to further complications.

As a rule, acute cholecystitis does not offer a difficult problem in diagnosis. The symptoms are usually confined to the right upper quadrant and may consist of a steady severe pain or attacks of colic, with a fever of 102 F. or higher and a high leukocyte count often of 15,000 to 25,000. If empyema develops, a chill may occur. There is localized rigidity and marked tenderness. The pain may remain localized or be referred to the right scapular region and usually requires morphine for relief.

In the elderly and the greatly debilitated, including those who suffer a severe toxemia, drainage rather than removal of the gall bladder may be the safer surgical procedure. Also, in the presence of a marked inflammatory reaction that has involved the ducts and obscured the anatomy, cholecystostomy may prove a wise choice. Otherwise, we prefer to do a cholecystectomy, working from the ducts upward. A small drain is removed after five days. For the past two years we have had our patients out of bed in most instances after twenty-four hours and walking after the second postoperative day. We have reduced the use of duodenal suction and intravenous fluids, believing that early ambulation, by stimulating peristalsis and the circulation, has permitted the patient better to tolerate oral feeding and to maintain normal digestion and that speedier healing of the wound has resulted.

Intestinal Obstruction

The surgical mortality of this condition for years was listed as close to 50 per cent by many of our leading hospitals. Improved methods of diagnosis, a better understanding of the principles of the treatment involved, and earlier operations have considerably lowered the surgical mortality in the past few years.

In any acute abdominal complaint a careful search should be made for the presence of operative scars. An operation performed many years previous for a ruptured appendix may be the cause of an acute intestinal obstruction. Failure to carefully peritonize the cervical stump following a subtotal hysterectomy may give rise to an intestinal obstruction. Similarly, if the gall-bladder bed is not peritonized after a cholecystectomy, a loop of gut may become adherent and obstructed. Acute obstruction from cancer of the bowel is one of the most commonly seen lesions of this type. Volvulus in the elderly, intussusception in children, and strangulated hernia at any age are other causes of obstruction. Separation of the wound after an operation may allow a small loop of bowel to become obstructed, or a gallstone may perforate into the small intestine, giving rise to similar trouble.

One reason the mortality rate is high is because these cases often come to the operating room too late. When marked symptoms of toxemia are present, the diagnosis is not always easy to make because the symptoms may be atypical at first. The temperature, pulse, and respiration may be normal. If the obstruction is high, vomiting may occur early, but if it is in the colon, the symptoms are more of obstipation and a failure to pass gas. Colicky attacks of abdominal pain may occur, visible peristalsis may be seen, and distention is usually present. A flat x-ray plate of the abdomen may show the typical stepladder appearance of intestinal obstruction. So-called fecal vomiting, the inability to obtain results from enemas, and the failure of mineral oil to pass are all indicative of obstruction.

If a complete mechanical obstruction does not exist, the Miller-Abbott tube may relieve the condition, but its manipulation requires adequately trained personnel. If a true obstruction is present, the sooner it is surgically relieved the better.

Regional Enteritis

Regional enteritis, first described by Krohn and his associates at the Mount Sinai Hospital in New York in 1932, is now a well-recognized entity, although not commonly seen. This disease varies in its symptomatology and in the first phase may simulate acute appendicitis. In the second stage it may resemble acute ulcerative colitis, and there may be secondary anemia with fever and diarrhea. In the next phase obstructive symptoms occur, and finally multiple fistulae develop between loops of intestine or the bladder. The etiology of this condition remains unknown.

Surgical opinion is not unanimous regarding treatment, some preferring resection of the diseased intestine and others merely advocating sidetracking of the involved area. In some instances the appendix is removed and the regional enteritis overlooked at the primary operation. A persistence of symptoms then necessitates an x-ray study which may show the characteristic "string" sign appearance of the barium as it passes through the greatly diminished lumen of the bowel.

Mesenteric Lymphadenitis

Mesenteric lymphadenitis is another condition that may so closely simulate appendicitis that a diagnosis cannot be determined without operation. Fever, elevation of the leukocyte count, pain, tenderness, and nausea may occur. To confuse the picture further, it is most frequently seen in children and young adults. The pains are apt to occur on either side and to be fleeting in character; rigidity is uncommon. Tenderness may be bilateral. Because over 90 per cent of the patients I have operated upon in a series of nearly 200 cases have drunk raw milk, I believe this disease is possibly bovine in origin. In my experience it rarely is seen in city children who have been raised entirely on pasteurized milk. If, however, these children spend a summer or two on a farm and drink raw milk, they too may develop mesenteric lymphadenitis. This theory is contrary to that of Wolinsky who maintained that these glands are secondary to a respiratory infection and are similar to enlarged cervical glands in the neck.

It was my good fortune to hear the first paper given on this subject in this country which was presented by the late Doctor Leonard Freeman at Saint Paul in 1922 at a meeting of the Western Surgical Association. It was a classical paper, and little has been added to our knowledge of the subject since that time. Pathological study of the glands has failed to reveal the origin of the disease. The glands vary markedly in their size and number and are usually encountered in performing an appendectomy for an acute or chronic appendicitis. If the glands are markedly enlarged and numerous and appear definitely more responsible than the appendix for the symptoms, the patient or parents should be advised that symptoms may persist for some months. These patients should go on a careful hygienic regime; they should drink pasteurized milk, and they should take sun baths, especially exposing the abdomen until it is well tanned.

Mesenteric Thrombosis

The classical picture of a rather elderly patient, known to have heart trouble and, in particular, auricular fibrillation, taken with an attack of abdominal pain, and passing blood from the rectum, is characteristic of mesenteric thrombosis. The abdomen may be moderately distended and present a rather doughy appearance. The important thing is to operate at once before gangrene has become extensive and, as soon as the diagnosis is established, to start dicoumarol and heparin to prevent a further extension of the thrombosis.

Appendicitis

Once I wrote a paper the title of which was "Half a Million Deaths from Appendicitis." The purpose of this was to point out that, despite improvements in hospitals, medical schools, transportation, laboratories, anesthesia, and the training of nurses and doctors, the mortality rate from this disease rose from 9.7 per cent per 100,000 population in 1900 to 12.8 per cent in 1936 and that in thirty years approximately 500,000 persons had died of this disease in this country. Notwithstanding thousands of articles and lectures on the subject both to layman and the profession, two persons were dying of appendicitis every hour until the introduction of the sulfonamides and penicillin. These drugs have effected a great reduction in the death rate, which has dropped from about 17,000 a year to probably less than 10,000 this year. This figure is still much too high. If everyone suffering from appendicitis could be operated upon before perforation has occurred, 98 per cent would recover. One statistical study compiled before the sulfonamides were used showed that of seven persons suffering from appendicitis and taking laxatives, six would die of peritonitis if not operated upon before perforation took place.

The sulfonamides have changed this. Since 1942 I have used 10 Gm. of sulfathiazole in saline routinely in the peritoneal cavity in perforated appendices and have closed all cases the past three years without drainage. No deaths have occurred; there have been no complications and no purulent discharges; and patients are usually out of bed in two days. Spinal anesthesia is used regularly; suction and intravenous glucose in saline is used ordinarily for only a day or two. More recently penicillin, 20,000 units, has been given every four hours, but as results were satisfactory before, this has only been used as an additional safeguard.

This entire paper could be devoted to appendicitis, and there would still be much left for discussion. It is impossible to discuss the varied symptoms that so frequently mask the picture. It is important to remember that the leukocyte count and temperature can be normal in the presence of a gangrenous appendix; that often pain is slight and rigidity absent; and that if the appendix is retrocecal, tenderness may only be elicited by turning the patient on his left side with the knees drawn up and having him breathe deeply. Experience is perhaps the best teacher, but even those whose experience is great may be puzzled by the occasional case. As a rule, it is better to operate when in doubt. A high polymorphonuclear count usually calls for surgery. Of the various incisions, I favor the pararectus incision in which the rectus is retracted to the patient's left. A purse string of silk is used with inversion of the stump, and the incision is closed with fine chromic gut as sulfathiazole is dusted into the various layers.

Space does not permit discussion of various other interesting examples of the acute abdomen, such as hemorrhage, perforation and strangulation from congenital anomalies as a Meckel's diverticulum, or of perforation of a diverticulum of the jejunum or the sigmoid, torsion of the omentum, rupture of the liver, spleen, kidney, or intestine from trauma, and bullet or stab wounds of the various organs. From the standpoint of diagnosis and treatment, each of these conditions, as well as numerous others, presents definite problems that only serve to make this field of surgery perhaps the most intriguing and satisfactory.

When this subject was presented before the St. Paul Surgical Society, mention was made of the fact that early ambulation, the intraperitoneal use of sulfathiazole, the use of early oral feeding in preference to intravenous therapy, the replacement of enemas by mild laxatives and bathroom privileges and of bulky dressings by Mediplasts had simplified the work of our staff and improved our results. There is every indication that chemotherapy will play a still greater part in the future in lowering the mortality of acute abdominal conditions.

According to the Statistical Bulletin of the Metropolitan Life Insurance Company for February, 1946, the death toll from appendicitis dropped from 18,000 a little over a decade ago to 8,100 in 1943. Doubtless this figure has been lowered since 1943. The death rate fell from 9.9 to 6.1 per 100,000 from 1940 to 1943. Credit for this improvement is given to the use of chemotherapy in cases complicated by peritonitis and to the national publicity campaign which has warned against the use of cathartics and the importance of prompt medical attention in the presence of abdominal pain.

THE USE OF MYRISTYL-GAMMA-PICOLINIUM CHLORIDE IN SURGERY

ARNOLD SCHWYZER, M.D.
Saint Paul, Minnesota

ONE of the oldest problems of surgery is skin disinfection and the attempted disinfection of wounds. Before the application of germicides, gross dirt and organic matter must first be removed, as they would inactivate the great majority of germicides. Preliminary cleansing with tincture of green soap is necessary for removal of gross skin contamination. Nevertheless Trueta[31] and Barnes[4] have had excellent success with detergents which cleanse the wound and also are bactericidal, while innocuous to living tissue. One of the detergents which they used, was cetyl-trimethyl-ammonium bromide, a member of the group of quaternary ammonium salts.

The harsh chemicals which are used for skin sterilization do a great deal of harm in treating open wounds and burns, besides forming a thicker, less pliant scar.[9] In 1908 Grossich[12] introduced tincture of iodine for skin disinfection, but its activity has been questioned.[28,29 30] Of the heavy metals, mercury has been the most popular. Later, simple mercury salts were replaced by organic mercurials, as metaphen, merthiolate, furmerane, and phenyl mercuric nitrate, which were found to be many times more powerful.[5,11] Phenol causes skin necrosis. Lysol is a 50 per cent solution of a mixture of ortho, meta, and para-cresol and is three times more bactericidal than phenol, and only slightly toxic, though not completely innocuous.

Halogenation trebles bactericidal action of coal tar acid dyes, but it decreases solubility. Dettol is one of this series. Mercresin[8,21] is alcohol-acetone solution of penta-cresol and an organic mercurial, ortho-hyroxy-phenylmercuric chloride (mercarbolide.) Pentacresol is a mixture of five isomeric amyl cresols, derived from alcohol and cresol. While both components are strong, Maddock reports a synergistic action of the two, which is 200 to 300 per cent greater than the sum of the action of the two. Another disinfectant, which is somewhat weaker, is alcohol-acetone solution of tri-cresol and mercuric chloride, Novak's solution.[24] In 1935 Vaichalis and Arnold[32] showed that the solvent alone, 50 per cent alcohol and 10 per cent acetone, kills 96 per cent of the bacteria on the skin.

In an open wound or burn, none of the above chemicals has any use as they cause tissue damage, and devitalized tissue is an excellent medium for growth of bacteria. Iodine is very toxic to tissues and is inactivated by blood. The mercurials retain a fair percentage of their activity in serum protein, but they are extremely toxic toward leukocytes. Mild neutral soap solutions may be used, but tincture of green soap is far too toxic.[1,19]

Friedrich[10] in 1898 distinguished between fresh wounds, merely contaminated, and wounds in which inflammatory infiltration of the surrounding tissues has already occurred. He found that an interval of six to eight hours is necessary for multiplication of the bacteria and their invasion into neighboring tissues. Owing to extension of infection it appears highly unlikely that treatment of the surface of wounds will eradicate the infection. Remarkable healing of old wounds and infections can be accomplished by uninterrupted rest, immobilization, and light pressure, which principles have been described by Wangensteen and Koch.[20,33,34] In the past there have been several factors which have been considered as the possible cause for the non-healing of wounds, even uninfected wounds. Four factors have come into consideration. These are as follows: (1) removal of granulation tissue; (2) restricted circulation due to edema; (3) presence of a serum exudate; (4) lack of maintenance of compression to promote circulation.

Subsequently, prominent surgeons in the United States further improved the treatment of wounds. Reid[25,26,27] observed that healthy granulation tissue can overcome bacterial contamination and also that granulation tissue is very resistant to the spread of infection and should not be debrided or disturbed. Further, Reid[27] found that edema, causing restricted circulation, delayed healing of wounds, which was attributed to the exudation of serum and prevented the formation of a fibrinous medium necessary for growth of epithelial cells. Koch[20] has also focused attention on compression, not constriction, as a factor in the treatment of wounds, compound

This work was supported by a grant from the Upjohn Drug Company, Kalamazoo, Michigan.

fractures, and burns to prevent loss of body fluid and maintain circulation.

* * *

As early as 1916, Jacobs and Heidelberger[14, 15,16] described the germicidal activity of quaternary ammonium salts derived from hexamethylenetetramine. In May, 1935, Domagk[7] of the German I. G. Farbenindustrie published in the *"Deutsche-Medizinische Wochenschrift"* an article which showed further studies relating to germicidal power of quaternary ammonium salts. Though these salts are excellent detergents themselves, their action is reduced by the soaps. As mentioned above, during the Spanish Civil War (1936-38) Trueta[31] and Barnes[4] reported excellent results with their use, especially cetyl-trimethyl-ammonium bromide. In 1940 Miller and Baker,[22] and in 1941, Harrison and Miller[3] compared the *in vitro* properties of soap and certain cationic detergents. As soaps contain an alkyl radical with a negative charge, they are classified as anionic detergents. Cationic detergents were found to be more general inhibitors of bacterial metabolism than anionic detergents, according to measurements made in the Warburg manometric apparatus. Maximum inhibition was found with compounds of twelve, fourteen, and sixteen carbon atoms, lauryl, myristyl, and cetyl respectively.

Brown et al. have found that the use of phemerol (paratertiary-octyl-phenyl-diethoxy-dimethyl-benzyl-ammonium chloride) to be superior to tincture of green soap and alcohol, and cresol-mercurials, and halogens. Another member of the group of quaternary ammonium salts is cetylpyridinium chloride (Ceepryn), which also has been found to be very powerful.[13] Zephiran is the third quaternary ammonium salt on the market at the present.

Another quaternary ammonium salt is myristyl-gamma-picolinium chloride (quatresin). Dr. Marie Moorhead[23] at Ohio State University has done extensive bacteriological studies on quatresin and compared it with the other quaternary ammonium salts. Against staphylococcus aureus it is somewhat more powerful and is equally powerful against typhoid and dysentery.

Both tincture of quatresin, 1-500, in alcohol-acetone solution (50 per cent alcohol, 10 per cent acetone, 40 per cent water) and aqueous solution, 1-1000, are now available and have been used rather extensively on the surgical service at the Minneapolis General Hospital. At first the tincture was used for skin sterilization in minor cases only, and in a series of approximately one hundred cases, as insertion of Kirshner wires, Steinmann pins, Roger Anderson pins, and also the removal of metallic fixation, as nails, screws, etc., no infection developed postoperatively. Subsequently it was used as the routine disinfectant on the fracture and orthopedic services, and it has been used in approximately 300 major orthopedic cases. Also, it has been used for pre-operative preparation in about one hundred and fifty cases of abdominal surgery. The only infection encountered in this series occurred in an open reduction of a hip, with open arthrotomy, which proved to be far more tedious than usual and in which the infection appeared fifty days postoperatively. With hot packs and penicillin, the infection which proved to be caused by a hemolytic streptococcus, not an ordinary wound contaminant, cleared up in a few days.

Solution of quatresin has been used as packs for preliminary pre-operative skin cleansing. In about fifty cases of herniorrhaphy packs of solution of quatresin have been applied to the inguinal region for about twenty minutes, during which time the patient was shaved. This was done in patients who were excessively heavy and whose personal hygiene was poor. After the application of packs the routine skin preparation with tincture of quatresin was carried out. None of these cases showed any drainage or reaction at the site of the surgical wound. Aqueous solution of quatresin has also been used for irrigating minor abraisions and lacerations and about fifteen compound fractures. In a much larger series of compound fractures, thirty-five, treated by the technique in use at the Minneapolis General Hospital,[17,18] the skin was prepared with tincture of quatresin, and the irrigation of the wound was done with saline. No infection developed, though control is lacking as during the previous five or six years a large proportion of the compound fractures healed per primum, with infection in less than 10 per cent.[17,18]

Aqueous solution of quatresin has also been used rather extensively on the gynecological service. The solution is non-irritating and has been used as a vaginal pre-operative disinfectant in about one hundred cases. As the solution is colorless, a few drops of the tincture, which is tinted, have been added to obtain a colored solution in order to reveal the area which has been prepared.

Experimental

An attempt was made in the laboratory to determine whether irrigation of a contaminated wound with solution of quatresin could rid a wound of contamination to a greater extent than irrigation with physiological saline. Methods devised to study infection in animals always entail great difficulty in the control of many factors which influence the course of the infection. Control of virulence of the organism is only one of the factors which has to do with the creation of infections which are similar in different animals. Mice are usually used in assaying the potency of the culture. The organism may be introduced intraperitoneally with the various drugs to be tested being administered either orally or by the intraperitoneal route. By varying the number of organisms injected and the dose of the drug used, the comparative efficiency of the drugs can be assayed with a fair degree of accuracy.

An evaluation of the effects of bacteriostatic agents which are implanted in contaminated wounds is even more difficult. Organisms introduced into wounds of the skin, or introduced through a needle into the subcutaneous tissue, give rise to widely varying lesions in different animals. This is true even when frozen or lipholized organisms are used. The effect of the addition of the drug to be tested when added to such contaminated wounds has, in our hands, been impossible to interpret with exactness. A determination of the tension required to separate wound edges is of value if one is studying wound healing. As our criteria we chose to determine the presence or absence of the introduced organisms following the application of the drug used in the particular test.

Preliminary bacteriological studies on quatresin (myristyl-gamma-picolinium chloride), carried out by Dr. Marie Moorhead at Ohio State University, indicate that the drug can be diluted 1-85,000 and still be effective in killing a standard strain of staphylococcus aureus *in vitro*. The effective dilution of quatresin was reduced to 1-12,000 when 10 per cent horse serum was added to the culture medium. One would expect this effective concentration to be further reduced if the drug is placed in a wound where serum and blood are present in large amounts.

For our work, we chose the living animal, the dog, rather than the *in vitro* method of Dr. Moorhead. The test organisms chosen for our work was a hemolytic, coagulase-positive staphylococcus aureus freshly isolated from a fatal human bacteremia. Previously Altmeier and Gibbs[2] had shown that the staphylococcus is the most common wound contaminant, and accordingly it was selected. As it proved rather difficult to produce a virulent infection in dogs, the hemolytic variety of staphylococcus was used, which is a rare variety in wound infections. To adapt this organism to the dog, repeated intravenous transfers from dog to dog were carried out. A total of six passages was necessary before a small dose (1.0 c.c. of a 24-hour broth culture) would kill the dog in eighteen to twenty-four hours. This culture was maintained on agar slants in the icebox. It is recognized that this was not the ideal method of maintaining uniformly virulent organisms. However, since most of the animals had two wounds, one the donor site from which a bone graft was removed and the other the host, it was possible to have a control. In addition we were examining for the presence or absence of the organisms in the wound; therefore our interest was primarily in a strain of staphylococcus that was capable of existing in a control wound for at least twenty-four hours. Twenty-four hours before the wound was to be contaminated, the organisms were taken off the agar slant and transplanted to a tube of nutrient broth. This was then diluted 1-100, and 1.0 c.c. was injected into the wound. Repeated plate counts showed that the count never varied over a thousand organisms per c.c.

A series of experiments were carried out in which a bone graft was removed from the tibia of a dog and implanted into the femur, where it was held with two or three vitallium screws. Since treatment of compound fractures practically always involves the use of some internal fixation, which is a foreign body and tends to keep infection alive, it was thought that this experiment would reveal the difference in results obtained when a wound is irrigated with solution of quatresin or with saline. Also in some compound fractures it is advisable to leave large loose pieces of bone in the wound, as their removal would leave too large a gap and lead to non-union. The donor site was also inoculated and left untreated. Cultures from this area were always positive for staphylococcus aureus. The grafted site was then used as a test area, and cultures were taken forty-eight hours after treatment. A uniform proce-

	6,000,000	18	Saline	4 plus
2545	6,000,000	18	None	4 plus
	6,000,000	18	Saline	4 plus

dure was worked out for culturing the wounds. The wound was spread, and swabs were taken from the infected area. At least five swabs were individually introduced into melted agar, cooled at 45°C. and then poured into a petri plate. These five plates were incubated for forty-eight hours, and counts were made at the end of the incubation period. If the counts were from 500-1000, they were recorded as 4 plus; 200-500, 3 plus; and 100-200, 2 plus. The errors in this procedure are recognized, and little significance was attached to the results unless all five plates had fewer than ten colonies per plate. This was picked as our criteria since we were interested in sterilizing the contaminated area.

In Table I summaries of four animals are presented. The organisms were introduced immediately after operation. Quatresin solution was used in the form of an irrigant before the wound was closed. The time of contact of the germicide was approximately twenty minutes since that was the time necessary for the quatresin to run in. Besides the effect of the quatresin there was the added effect of mechanically washing the organisms out. To control this, one dog received a saline irrigation instead of the quatresin.

In these experiments the donor site was used as a control and received no therapy. Experiments number 316 and 319 were carried out in a little different manner in that the inoculum size was increased, and no control site was used. It will be noted that the increased size makes considerable difference in the efficiency of the quatresin. For this reason, the following experiments were carried out with the increased inoculum.

In the second set of experiments, the operation and infection were carried out as before. However, an eighteen-hour incubation period followed before irrigation with quatresin was started. From these data it was hoped that some conclusions could be drawn as to the efficiency of quatresin in combating postoperative infections.

From the preceding experiments one can conclude that it is impossible to sterilize a wound that is already infected with a hemolytic staphylococcus, especially, when the inoculum is as large as 6,000,000 organisms and the infection has persisted for eighteen hours prior to treatment. A series of experiments were then carried out in which the infection time was reduced to one hour. The errors of mechanically washing the organisms out of the wound before they had time to cause infection would then be partially eliminated.

In the next series of experiments the femur of the dog was exposed by separating the vastus lateralis muscle from the rectus femoris muscle. The inoculum was introduced into the wound, and one hour later the irrigation was carried out. Two days later the culture was taken.

Discussion

Tincture of quatresin has been found to be an excellent pre-operative surgical disinfectant, after Dr. Moorhead had demonstrated its strong germicidal action by laboratory methods and compared it with other quaternary ammonium salts.

The tincture of quatresin has been found to be an excellent skin disinfectant and has been used extensively at the Minneapolis General Hospital.

Also tincture of quatresin has been used as a skin disinfectant in the Surgical Laboratory at the University of Minnesota. Dr. Baronofsky of the Department of Surgery at the University of Minnesota has used it in about 150 cases of in-

TABLE III. QUATRESIN AS A POSTOPERATIVE DISINFECTANT

Experiment Number	Inoculum Size	Infection Time (hr.)	Therapy	Cultures
325	6,000,000	1	Saline	4 plus
327	6,000,000	1	Saline	4 plus
225	6,000,000	1	Quatresin	3 plus
313	6,000,000	1	Quatresin	2 plus
315A	6,000,000	1	Quatresin	0
331A	6,000,000	1	Quatresin	0
331B	6,000,000	1	Quatresin	0
47A	6,000,000	1	Quatresin	0
47B	6,000,000	1	Quatresin	0
423A	6,000,000	1	Quatresin	0
423B	6,000,000	1	Quatresin	0
424A	6,000,000	1	Quatresin	1 plus
424B	6,000,000	1	Quatresin	0

testinal anastomosis carried out in the laboratory. There was no case of infection and all the wounds looked cleaner and showed better healing than when the old method of iodine, which was later removed by Richardson's solution, was used.

The aqueous solutions of quatresin can be used freely on any open surface and in the early stages it is definitely superior to saline. No toxic reactions have been found from its use. In one experiment it was injected into the hip joint of a dog and microscopic slides showed the cartilaginous surfaces to be the same as on the control side. Similarly the solution was poured into a trephine opening in the skull. Except for surgical intervention there was no reaction.

Even though infections have been prevented by its use in the early stages, it has no effect on late case. For such cases one must rely entirely on the principles of rest, immobilization and light pressure, after a proper debridement has been done, all of which are indispensable also for treatment of early injuries.

Summary and Conclusions

An attempt was made to evaluate quatresin (myristyl-gamma-picolinium chloride) with respect to its efficiency as a disinfectant in surgical procedures to eliminate infections, both in wounds without foreign bodies and wounds with foreign bodies, i.e. screws and bone grafts.

1. It has been shown that wounds infected with 6,000,000 organisms, per c.c. can not be sterilized by the use of quatresin when it is used as an irrigant immediately after surgical manipulation, providing a bone graft which is a real foreign body, is implanted into the wound. If the inoculum is reduced to 4,000,000 organisms per c.c., quatresin will sterilize the wound.

2. If treatment with quatresin is delayed eighteen hours after the introduction of the organisms, there is no effect, as with any other disinfectants.

3. If quatresin is used in the form of an irrigant one hour after surgery, varied results are obtained. The tables show the superiority of quatresin over saline.

TUBERCULOUS PERICARDITIS

Incidence at Glen Lake Sanatorium

E. FENGER, M.D. and OLGA S. HANSEN, M.D.
Oak Terrace, Minnesota

TUBERCULOSIS of the pericardium has been called the least common and the most serious of the tuberculous infections of the serous membranes and was considered a rare disease by the early writers. Rokitansky is credited[7] with the first mention of it in literature in 1852 and the first clinical case was reported in 1872. Osler[7], in 1892, reported seventeen cases and observed that only twenty-seven references had appeared in the *Index Medicus* to date and that only five cases had been described in the *Transactions of the Pathological Society of London.*

The literature after 1900 shows an increasing number of reports with a fairly consistent rate of occurrence. Isolated case reports became more numerous and the collected series indicate a fairly constant incidence of about 1 per cent in all autopsies and 4 per cent in those with tuberculosis. Occasional collections, as those from South Africa with a large colored population, show a much higher rate. Antemortem recognition is still the exception as judged by the reports from numerous hospitals.

To our surprise, the Glen Lake autopsy records of 1,292 tuberculosis patients show tuberculosis of the pericardium in only nineteen, that is, 1.5 per cent as compared with 4 to 6 per cent elsewhere. Our proved clinical cases make a total of twenty-two in a patient population of 8,578, or .25 per cent. The fact that Minnesota as a state has one of the lowest rates of morbidity and mortality for tuberculosis may account for the infrequency of this very serious complication. Doctors Charlotte Van Winkle and George Higgins have performed the autopsies in almost all cases, thus giving assurance of zeal and accuracy.

Incidence percentages differ in our small group from those reported in the literature in every respect but one, that of mortality, namely 80 to 90 per cent. Thompson considers tuberculous pericarditis to be a disease of the elderly from forty-nine to eighty-four years of age with an average of sixty-nine. Keefer[5] and also Blalock and Levy[2] find it predominantly in those past forty. In the Glen Lake group over half of the patients are between twenty and forty.

As to sex, Blalock and Levy[2], and Whitehill[3] found males in the great majority (85 and 86 per cent, respectively), whereas our cases are almost equally divided between males and females.

The clinical and pathological features of the disease have been described in detail in many published case reports. In sixteen cases in our series, the diagnosis was made at autopsy only, although in three, electrocardiograms were taken, presumably because of a suspicion of heart involvement. Ten showed dense fibrous adhesions or obliteration of the pericardial sac, indicating old healed or healing lesions. Hypertension with hypertrophy of the left ventricle occurred in one of these. Four had fresh fibrinous adhesions or minute fresh tubercles denoting an acute process. Two had a combination of old and recent pericardial involvement.

Only six cases were diagnosed clinically, all with pericardial effusion. Tubercle bacilli in the fluid or guinea pig inoculation gave positive proof. Three of the six patients died of progressive tuberculosis of the lungs. The other three with tuberculous pericarditis as the major cause of illness will be reported in more detail. They recovered from the acute pericardial disease, but one died of portal cirrhosis some months later. Summaries of the three recovered cases are reported.

A. K., a housewife, aged thirty-six, was admitted April 17, 1939. Her illness began late in January, 1939, with dyspnea, malaise, and weakness. During the past ten years, she had suffered four distinct attacks of painless jaundice associated with nausea lasting from one week to three months. Her pericardial effusion was aspirated and by guinea pig, proved to be tuberculous. The effusion was treated by open drainage with catheter. The lungs were negative for tuberculosis. After her acute pericardial disease had subsided, she was sent to the sanatorium for further treatment and because genitourinary tuberculosis was suspected. Tubercle bacilli were not found in the urine, and cystoscopy and pyelograms were negative. After five months, when she was improved and about to be discharged, she developed jaundice with a palpable spleen and liver. Signs of pneu-

---

Presented before the Minnesota Society of Internal Medicine, Saint Paul, Minnesota, October 15, 1945.

monia appeared and she died on October 18, 1939. Autopsy revealed the cause of death to be portal cirrhosis and bronchopneumonia. The pericardial sac was obliterated by dense fibrous adhesions.

C. B. was admitted on February 16, 1935, at the age of thirty-six years. He had been a patient at the State Sanatorium from September, 1932 to April, 1934, with tuberculosis, moderately advanced. In November of 1934, an enlarged gland in the cervical region was found to be tuberculous. X-ray plates showed tuberculosis, moderately advanced with a spread. On admission to the Glen Lake Sanatorium, he had malaise, fever, and cough. The sputum was negative for tubercle bacilli. Bed rest and routine sanatorium care resulted in arrest of the pulmonary process and discharge on December 4, 1935.

He was readmitted November 7, 1936, complaining of malaise, slight cough, anorexia, and dyspnea on exertion. His temperature suddenly rose to 104 degrees. A clinical diagnosis of tuberculous pericarditis was confirmed by x-ray. The heart sounds were distant and a friction rub was present. Guinea pigs injected with the pericardial fluid died of miliary tuberculosis. The lung lesion was considered to be inactive. He gradually improved on routine care, was discharged as quiescent after six months (May 23, 1937) and has remained well and able to work for the past eight years.

R. L., a housewife, aged thirty-five, was well up to January 10, 1943, at which time she noticed edema of the ankles; and on February 25, 1943, she had chills, fever, extreme weakness, dyspnea and pain in the left chest. Pericardial effusion was found and aspirated. Tubercle bacilli were isolated from the aspirated fluid. The lungs were negative for tuberculosis on x-ray examination. On bed rest, the effusion gradually began to disappear and the symptoms subsided. In November of 1943, peritonitis appeared; in December of 1943, right pleural effusion; and February of 1945, left pleural effusion. Gradual improvement of these complications took place. She is now clinically well and will be discharged in December of 1945.

Conclusions

1. Only twenty-two cases of proved tuberculous pericarditis occurred in 1,292 autopsies and in 8,578 patients (1.5 per cent of autopsies and .25 per cent of patients).

2. Sixteen cases were diagnosed at autopsy without clinical recognition. Six cases were diagnosed clinically. Three died of the disease.

3. Tuberculosis of the pericardium is, at Glen Lake Sanatorium, a rare complication of tuberculosis with a grave prognosis.

SEROLOGIC TESTS FOR SYPHILIS

The Frequency of Positive Serologic Tests for Syphilis in Relation to Occupation and Marital Status Among Men of Draft Age. Lida J. Upsilon, Paul T. Bruyere and Martha C. Bruyere. Journal of Venereal Disease Information, Washington, 26:216-222, (Oct) 1945.

An analysis based on information concerning occupation and marital status for a random sample of men examined for Selective Service showed that the prevalence of syphilis varies widely among different occupational groups. It also showed that in any occupation group the prevalence of syphilis is substantially higher among single white men than among married white men but the differences between single and married groups among nonwhites was small.

The analysis was based on the results of serologic tests for syphilis performed on 531,236 Selective Service registrants who constituted a 20 per cent sample of the men examined from January 1 through May 31, 1945. Blood tests were tabulated according to age, race, marital status, and eleven broad occupational groups.

The prevalence of syphilis among single white men ranged from one or two per thousand for seventeen-year-old men in each occupational group to approximately thirty per thousand for the thirty-seven-year-old men in the professional group, fifty per thousand for proprietors, forty-five per thousand for clerical, forty-five per thousand for salesmen, eighty per thousand for craftsmen, eighty per thousand for operatives, eighty-five per thousand for service workers, and ninety per thousand for laborers.

The prevalence rates for married white men were 25 to 50 per cent lower than for single white men in corresponding occupational groups. In general among the white men, the differences between the syphilis rates of single and married men were much greater than were the differences between occupational groups, and these differences were least in those occupational groups having the highest syphilis rates.

Among Negro men a tendency for higher prevalence rates among the less skilled occupational groups was apparent but not statistically significant, and no statistically significant difference between married or single groups could be demonstrated.

The rates for the several occupational groups of Negro men ranged from about twenty per thousand among seventeen-year-old single Negroes in the more highly skilled occupational groups to more than 300 per thousand among thirty-seven-year-old Negro men in unskilled groups.

Prevalence rates for students were lower than for other groups on the whole. Rates for men other than married or single were compared, as a group, and the comparison showed that white men in this group had significantly higher rates than either the single or the married men in corresponding age groups.

THE ACCELERATION OF BONE PRODUCTION BY USE OF GROUND BONE

LUDOLF J. HOYER, M.D.
Windom, Minnesota

THIS study was occasioned by observation of the long healing period required for massive bone grafts and of the need for devising means to accelerate this process. The renewal of a removal strut or framework of quiescent, passive bone is well characterized by the term "creeping substitution."

It has long been thought that if bone were reduced by grinding to bone dust and suspended in blood or plasma[2] to the consistency of a paste revascularization and other simultaneous dependent processes should be facilitated and result in real saving of time in production of bony union.

As the first step in trying this conception a grinding device was contrived. Segments of long bone in experimental animals were removed and replaced with bone chips in one extremity and as ground bone paste in the other. The only variable was the size of bone mass or particles. Bone production for each procedure was followed by x-ray and in the gross after sacrifice of animals.

In a series of rabbits the periosteum over the fibulae was incised and reflected, and the total fibulae removed under ether anesthesia. Within the periosteal sheaths of the left fibulae in all the rabbits ground bone paste was inserted. Adjacent muscle and fascia were loosely approximated and the skin edges united with fine silk suture. The right fibulae in half of series were replaced by 1/16 inch to 1/8 inch segments of bone. The right fibulae were discarded in the other half of the series. Closures were made similar to those on the left.

The optimum time for comparison of bone production following these procedures was found to be three weeks. After this time had elapsed the rabbits were killed and the extremities were x-rayed and examined in the gross.

Representative films (Figs. 1, 2, and 3) show bone production three weeks following splitting of the periosteum and replacement with ground bone paste (*left* in each figure) and with bone chips in (Fig. 1, *right*) and regeneration from periosteum alone (Fig. 2 and 3, *right*). The structure of the sectioned fibulae is still apparent, indicating incomplete substitution by new bone. Production of bone from a paste of ground-up fibulae was from two to three times that present in the right fibulae.

The weight of fibulae averaged 0.4 grams for regrowth from ground bone, 0.27 grams from bone segments, and 0.19 grams from periosteal bone production *per se*.

It is believed that this study has important applications in the care of fractures, in other orthopedic situations and in plastic surgery. This concept represents no radical departure from accepted practices since bone dust from the sawing of bone has long been conserved and used. The obtaining and converting of rongeured bone chips to bone dust in paste suspension is technically simple and rapid. There is less manual handling of bone; consequently it is easier to maintain asepsis. The bone paste can be delivered into a syringe and accurately applied by touch or under fluoroscopic guidance. Operative time is reduced since the bone does not have to be shaped and chips tediously placed.

An advantage inherent in the use of this medium is the economy in donor bone needed. On test a given volume of bone produces three to five times its volume as powder and six to twelve times the original volume when suspended in fluid, the ratio being dependent on the proportions of cortex and cancellous bone, fineness of grind and density of suspension. Thus the bone volume taken is only a fraction of that required for chip fill-in or shaped grafts (true even if the donor defect is also filled in with suspension).

Clinical applications suggested by this study includes the following:

1. Filling in defects in length and cross section of bones. The cavity formed by excision of scar tissue can be filled in with bone suspension to supplement bone formation from an onlay graft or the bone suspension may be used alone with plate retention.

2. Filling in defects of skull, nasal, malar, and other bones by open surgery, by injection through a needle for lesser depressions, or by precast shapes[3] using ground bone or cartilage.

3. Accelerating repair when delayed union or non-union may be anticipated due to interposition,

---

Dr. Hoyer is now a captain in the Medical Corps of the Army.

distraction, or fractional contact of bone ends. Needling and puddling may be effective in forcing aside or impregnating with multiple tracts of suspension the interposed tissues or gaps in contact.

Present emphasis in orthopedic practice is on the use of thin strips of cancellous bone obtained from the ilium as a filler for orthopedic defects.[1] Use of ground bone suspension has a like merit and additional distinct applications. The cancellous element of a rib is similar to that of the ilium in its bone producing quality, is easier to obtain and its cortical element provides in ground-up state diffuse, minute, local depots of the components with which osteoblasts lay down bone. Vascular exchanges make these quickly available by way of a rapidly established vascular bed.

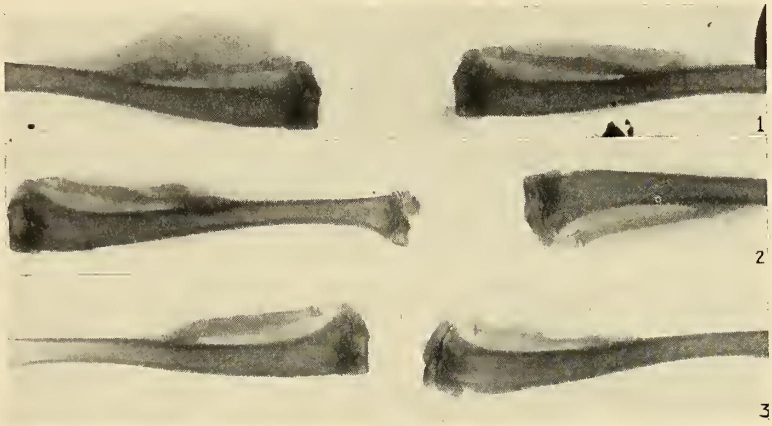

Fig. 1. X-ray three weeks after removal of fibula and replacement with ground bone paste *(left)* and bone chips or segments *(right)*.

Fig. 2. X-ray of extremity of another rabbit three weeks after removal of fibula and replacement with ground bone paste *(left)* and regeneration from periosteum alone *(right)*.

Fig. 3. X-ray in third rabbit three weeks after replacement with ground bone paste *(left)* and regeneration from periosteum alone *(right)*.

Summary

Comparable defects were produced in left and right fibulae of rabbits, filled in with bone chips on one side and ground bone suspension on the other. Bone production from ground bone was found to be much more rapid than that from bone chips. This acceleration is due to ease of vascularization of a suspension. Conversely, a solid mass of bone offers time-using resistance to vascular invasion. Clinical applications are believed to be many and time saving.

THE FOOTPATH TO PEACE

To be glad of life, because it gives you the chance to love and to work and to play and to look up at the stars; to be satisfied with your possessions, but not contented with yourself until you have made the best of them; to despise nothing in the world except falsehood and meanness, and to fear nothing except cowardice; to be governed by your admirations rather than by your disgusts; to covet nothing that is your neighbor's except his kindness of heart and gentleness of manner; to think seldom of your enemies, often of your friends and every day of Christ; and to spend as much time as you can with body and spirit, in God's out-of-doors—these are little guideposts on the footpath of peace.—HENRY VAN DYKE.

GALLSTONE ILEUS

Report of Case

CARL B. DRAKE, M.D.,
Saint Paul, Minnesota

WHILE the treatment of gallstone ileus is surgical the diagnosis is just as much a problem for the internist as the surgeon.

A gallstone to produce intestinal obstruction must be large, probably 2.5 cm. in diameter or larger, and must erode its way into the small intestine. Because of the proximity of the duodenum to the gall bladder this is the usual site of the perforation although sometimes the fistulous track enters the jejunum, stomach or colon. A stone, free in the peritoneal cavity, may make its way into any part of the intestinal tract or even into the urinary bladder. It usually obstructs in the lower ileum where the lumen is narrower.

Bartholin in 1654 is credited with having first described a case of gallstone ileus. Courvoisier in 1890 reported on 131 cases and Von Wagner in 1914 on 334 cases which had appeared in the literature. Many isolated cases have been reported in the past twenty years but of the few articles which have appeared recently I have found the one by Rigler, Borman and Noble published in the November 22, 1941, *Journal of the American Medical Association* the most valuable. According to Hinchey, his case is the only one reported in which a second obstructing stone was removed during convalescence from the operative removal of the first one.

Gallstone ileus appears in the later decades, several times as often in women, 75 per cent of all cases being present in women over sixty.

The symptoms are those of intestinal obstruction with vomiting and colic which may be periodic. Some individuals have a history of gallstones, some of periodic digestive disturbance and some give a history of no digestive trouble until obstruction occurs. With high obstruction there is no distension.

The condition has to be differentiated from other types of mechanical obstruction and from paralytic ileus. A knowledge of previous gallstone attacks or x-ray evidence of the presence of gallstones is of value. In paralytic ileus gaseous distension is more marked and colic may be absent. Obstruction due to gallstone ileus does not respond to duodenal drainage any better than strangulation of the intestine associated with intussusception, volvulus, mesenteric thrombosis or obstruction due to new growths. Failure to deflate in any obstruction is an indication for immediate operation. As there is little or no distension in gallstone ileus there is a temptation to employ nasal suction too long. The leukocyte count and pulse are of little value in this condition whereas both tend to rise in obstruction due to strangulation.

X-ray is the most valuable aid in diagnosis. According to Rigler et al. only seven cases had been reported diagnosed by x-rays before 1935. From 1935 to 1940 twenty-four cases had been so diagnosed. In four of Rigler's fourteen cases the stone was visualized by x-ray. However in thirteen of his fourteen cases there was x-ray evidence indicating gallstone ileus. A most valuable x-ray sign is evidence of gas or if barium is used of gas and barium in the bile ducts. This is better demonstrated by a film of the upper right abdominal quadrant than with the tube focused over the mid-abdomen and is almost pathognomonic of a fistula from the duodenum into the gall bladder.

Treatment is, of course, surgical with preliminary deflation by duodenal tube and correction of dechlorination. Duodenal drainage should not be persisted in as the longer the drainage the higher the operative mortality. The mortality is at present about 50 per cent.

Report of Case

Mrs. E. G. S., a widow, aged seventy-five, was first seen February 4, 1942. She complained of right abdominal pain which had been present off and on all day followed by nausea and vomiting. On further questioning she admitted she had had the same pain off and on for four years but never had had any associated vomiting.

She stated she had had a stone removed from the left kidney twenty-five years before and had known she had high blood pressure for eighteen years.

On examination her blood pressure was 260/140, pulse 80, temperature 98.6. The abdomen was soft, borborygmi were present but there was no distention nor tenderness in the region of the appendix or gall bladder. The vomitus was grumous in character suggesting coffee grounds.

On admittance to the hospital the next day (February 5), physical examination was essentially the same, vomiting continued but the blood pressure was only 140/72. Over a pint of bile-colored fluid was drained from the stomach with relief. This material contained free HCl 17, combined acid 77, and occult blood. The leukocyte count was 8,000.

Nasal suction was instituted and intravenous glucose administered. A flatplate taken the day after admission (February 6) showed some gas in the stomach and colon but none in the small intestine and no gallstone.

The symptoms of obstruction persisting, a small amount of barium was given the fifth day after admission (February 11) and the x-ray showed a deformed duodenal cap and a non-opaque shadow about 4 cm. in diameter to the left of the spine and behind the stomach. No barium had progressed beyond the obstructing mass which was apparently in the distal duodenum. A tentative diagnosis of gallstone ileus was made.

The following day (February 12) a laparotomy was performed by Dr. J. F. Hammond. The gall-bladder region was occupied by adhesions and an inflammatory mass which extended to the region of the tail of the pancreas, suggesting an associated malignancy. Because of the inaccessibility of the mass back of the stomach a gastro-enterostomy was performed to relieve the obstruction.

After a stormy postoperative period of two weeks colicky epigastric pain, nausea and vomiting returned (February 27). A few days later (March 2), x-ray examination showed a functioning gastro-enterostomy, barium outlining the duodenum, gall bladder, common and hepatic ducts. There was no definite shadow of a gallstone but obstruction about six inches beyond the gastro-enterostomy site was almost complete.

The following day (March 3), a gallstone 2.5x2.5x3 cm. with a faceted surface was removed from the upper jejunum.

Convalescence from the second operation was stormy. A fistula developed and the drainage was copious for two or three weeks. The nature of the drainage fluids interfered with the healing and nutrition of the patient. She developed some indication of vitamin deficiency, a very red tongue, being present. Daily intramuscular injections of thiamine chloride and cevitamic acid were given for eight days and recovery followed with a slight fistula persisting.

The patient left the hospital, April 3, after two months in the hospital and later visited her daughter in Oskaloosa, Iowa. Her physician there was informed of her illness and the fact that the removed gallstone had a faceted surface and that she doubtless had or had had another stone.

On April 30 the patient had another attack of acute abdominal pain associated with nausea and persisting vomiting. X-ray showed an obstruction in the upper small intestine and on operation a second gallstone about the same size and at the same location as the previous one was removed. Convalescence was uneventful.

It is rather remarkable that this patient did not know previously that she had any gall-bladder disease. Her symptoms had apparently not been severe enough nor incapacitating enough to require x-ray investigation. Even during the period that the first gallstone was making its way into the duodenum she was not incapacitated. In spite of a high blood pressure for the past eighteen years and advanced years she went through three abdominal operations inside of three months without any circulatory difficulty.

PREPARATIONS EXEMPT FROM COUNCIL CONSIDERATION

The following official preparations have been declared exempt from Council consideration for inclusion in New and Nonofficial Remedies, as their actions, uses and nature are sufficiently well understood by physicians not to require such inclusion.

This list has been adopted for publication so that it may be brought to the attention of all manufacturers and other interested groups. From time to time there may be added other drugs, the names of which will also be published.

Iron and Ammonium Citrates
Ferrous Sulfate
Calcium Gluconate
Antimeningococcic Serum
Liver and Stomach Preparations included in U.S.P.
Digitalis Preparations included in U.S.P.
Acetylsalicylic Acid
Caffeine with Sodium Benzoate
Carbon Dioxide
Oxygen
Oxygen-Carbon Dioxide Mixtures
Chlorinated Paraffin (Chlorocosane)
Cinchophen
Neocinchophen
Dextrose Solution
Sodium Chloride Solution
Isotonic Solution of Three Chlorides
Sodium Citrate
Sodium Biphosphate
Magnesium Sulfate
Trioxymethylene (Paraformaldehyde-U.S.P. X.)
Methylene Blue
Quinine and Urea Hydrochloride
Salicylic Acid
Sodium Salicylate
Natural Oil of Sweet Birch (Methyl Salicylate)
Pentobarbital Sodium
Papaverine Hydrochloride
Emetine Hydrochloride
Totaquine
Tribasic Calcium Phosphate
Magnesium Trisilicate
Tribasic Magnesium Phosphate
Ichthammol Preparations
Strophanthin

MALIGNANT TUMORS OF THE KIDNEY

ARTHUR N. COLLINS, M.D., F.A.C.S.
Duluth, Minnesota

THE dictum that cancer is curable in its early stages may be difficult to demonstrate to our public if we try to prove it by our kidney-tumor cases. Even the most common symptom of kidney tumor, hematuria, which is the one that most often causes the patient to seek the physician's opinion, is frequently a manifestation of an advanced lesion. Hematuria must always be regarded with suspicion by the attending physician and should never be dismissed lightly. A normal urine may be present and the patient be the possessor of a malignant kidney. Howes observed that the prognosis in all renal cortical tumors is bad, since the growth may remain symptomless for an initial period and remote metastases may occur early.

Patients with prostate disease show hematuria frequently as one of their symptoms. This blood may not arise from the prostate however and these patients should be checked by excretory urograms for the possible presence of an associated kidney tumor. No tell-tale symptom aside from hematuria is yet available to us to arouse our suspicions of kidney tumor.

We are thus at a stage where late diagnosis, which is most often the case, necessitates radical surgery in an effort to cure our patient. In most cases we fail to cure because all tumor tissue is not removed. Even though the surgical mortality is low, the survival rate in terms of a three- to five-year period is low also.

This contribution is a review of thirty-two cases of malignant tumors of the kidney treated in St. Mary's and St. Luke's hospitals in Duluth in an effort to find, if possible, any encouraging factors in diagnosis or treatment. A tabulation of cases from the hospital records was made and the current literature on this subject was drawn upon. Most of the patients in this series died within two years after the onset of their symptoms.

Of the whole group only seven were alive at the time of this writing (March, 1945), one of whom was operated upon only one year ago. One patient survived five years, one patient four years, one patient three years, and three patients two years. All these patients were older than thirty-seven years. They all received nephrectomies. There was only one classified as of papillary type and the other six were adenocarcinomas.

Howes, in 1944, observed that in a series of fifty-four patients of this type only five survived over three and one-half years without evidence of metastases.

We are indebted to the roentgenologist for the helpful diagnostic evidence leading to incrimination of these malignant kidneys. In the light of our present knowledge the x-ray will have to be our guiding star if we can bring it into use earlier in the patient's illness. Loss of weight doesn't help us. One patient only in this survival group showed any loss of weight. Likewise a palpable mass was seldom helpful for in only one case of the seven was a palpable mass recorded. Pain was a feature in five cases but it was absent in two. The pain was located usually in the back or in the loin. One patient had pain in the right lower quadrant—a dull heavy ache. This pain however had been a complaint for three years preceding operation and hematuria was noticed during the same period of time; yet medical attention was unsought. In these seven cases one patient had hematuria two years, one had it six months, and two had it five months, one three months and one just a few days. Two patients had dysuria, however, and two had frequency of urination.

Turning to the twenty-five patients listed as "died," it was found that in four the history extended back several years as far as sixteen years in a case of papillary carcinoma, ten years in two cases, four years in one case and three years in two cases. This was precious time lost to these patients. Usually the patient is to blame for such delay because of lack of appreciation of the seriousness of his symptoms and also because, in the case of hematuria, the symptom is so many times painless. If pain were the dominant early symptom, patients would come to the physician earlier. When pain was mentioned in this group it occurred in the back or in the flank fourteen times. It occurred in the abdomen five times. There was no pain recorded in six cases. Pain occurs late in the course of the illness as a rule unless calculi are associated with the neoplasm.

One patient gave a "kidney stone" history extending ten years back and his symptoms were

---

Presented before the Duluth Surgical Society, October 18, 1945, and at St. Luke's Hospital Staff Meeting, November 22, 1945.

referred to the left. At autopsy he had a primary carcinoma of the left kidney and multiple remote metastases but there were no stones found.

A discussion of the roentgen diagnosis is important in these cases. Of the total group consisting of thirty-two cases, eight for sundry reasons were not referred for x-ray examination. Of the remaining twenty-four, thirteen had a positive x-ray diagnosis of kidney tumor. Eight more were regarded by the roentgenologist as "suggestive," which calls for a careful follow-up. Of the remaining three, one had a negative x-ray report and two were diagnosed as hydronephrosis. Obviously the last two required close scrutiny and follow-up also. This gives a high average of diagnostic assistance. Should the excretory urogram fail to reveal convincing facts, a retrograde urogram should be utilized. Melicow made the observation that a retrograde urogram is almost always conclusive in the diagnosis.

Le Conte discussed the antecedents of these kidney tumors and observed that pathologists occasionally find small cortical neoplasms which might exist perhaps for long periods as latent, silent or benign tumors. He mentioned the findings of Kozall and Kirshbaum who reported seventy-seven cases at autopsy, thirty-two of which showed small well encapsulated hypernephroid adenomata in the kidneys. The remaining forty-four were larger and termed hypernephroid carcinoma and some of these were associated with remote metastases.

Unfortunately we are at the present time devoid of diagnostic possibilities to reveal such neoplasms so early in the course of the disease.

Wilms tumor is the usual malignant tumor of the kidney found in children under seven years of age. However, in this series it is of interest that there was one case of Wilms tumor of the right kidney in a man aged sixty. This patient was admitted to the hospital for tonsillectomy in April of 1941. At that time no general examination was recorded. In May of 1943 he was admitted with swelling of the left leg and pain in the region of the left hip. Added to these complaints he had intense itching at various spots such as palms and soles, flexor surface of elbows and forearms which would be followed by localized swellings sometimes as large as hen's eggs. These swellings would last two or three days and then disappear. The urine was normal, hemoglobin 13.25 gms. (93 per cent), white blood cells, 8,850 and 10,950, polymorphonuclears 64 per cent, lymphocytes 31 per cent and monocytes 3 per cent. A biopsy of a neck gland was reported "inflammation of a lymphnode (mild)." X-ray revealed hypertrophic changes in the lumbar spine. Skin test using a drop of histamine intracutaneously provoked a large welt one inch in diameter within ten minutes. This disappeared in forty-eight hours. The patient left the hospital after eight days of observation with a tentative diagnosis of sarcoma, carcinoma or Hodgkin's disease and a palpable tumor in the left lower quadrant. A flat plate of the kidneys and bladder was said to be negative on this admission.

His next hospital admission was in June, 1943. The complaint was still of left leg pain and swelling and an increase in the size of a mass in the left groin. Some relief of his symptoms followed x-ray therapy and he left the hospital in five days.

He was hospitalized in August, 1943. This time a urologic examination revealed a bloody fluid coming from the right ureteral orifice. The catheter on the left side passed easily into the ureter but on the right the catheter would advance but a few centimeters. Bilateral retrograde urograms showed a marked filling defect in the right kidney. A probable tumor of the right kidney was diagnosed by Dr. Abrahams, the roentgenologist. At operation this right kidney was removed and the pathologist, Dr. Arthur Wells, recorded his findings as a Wilms tumor. To quote Dr. Wells "This tumor has the predominating elements of a fibro-sarcoma and in only one section did I find any carcinomatous elements. It should be noted that the tumor cells must certainly have been in a benign form as embryonal rests all of this patient's life. Dr. E. T. Bell (University of Minnesota) feels that this is a Wilms tumor." Herman states that such tumors in the adult are pathological curiosities.

There was one child of nine years who had a tumor of the right kidney which was diagnosed pre-operatively. Nephrectomy was done and at the time of operation it was noted that the renal vein was involved by tumor tissue as far as the vena cava. The autopsy report in this case disclosed embryonal adenocarcinoma with metastatic involvement of the liver, lungs, heart and adrenal.

One child, aged three, in this series, showed at operation a horseshoe kidney which was very low in the pelvis. On examination by the pathologist this kidney showed embryonal adenosarcoma.

A still younger child, aged two, was found to have a tumor of the left kidney, and this was determined in the laboratory to be an adenosarcoma.

Treatment is surgical in the adult cases, the majority of which will be adenosarcomas. In children, where Wilms tumors are usually found, radiation is the treatment of choice. According to Bixler, Stenstrom and Creevy, there are few, if any, five-year survivals in children with Wilms tumor. Where operation is contemplated for malignant kidney, in an adult, pre-operative radiation is advised by these authors on the basis that it stops the growth of the tumor cells themselves. On inoperable cases, life may be prolonged by radiation, and where metastases are present and accompanied by pain, radiation gives relief from pain.

Kerr and Stephens studied thirty-seven adult cases with respect to radiation. Some received radiation preceding surgery, some post operatively and some received no treatment other than radiation. One patient had been followed about ten years; twelve were living at five years. Eight of the twelve patients received radiation pre-operatively. These two men are of the opinion that pre-operative radiation decreases bleeding at the operating table.

Summary and Conclusions

A study of the histories of thirty-two cases of malignancy of the kidney with nephrectomy reveals many instances in which long periods of time had been allowed to elapse between onset of the symptoms and treatment. Inasmuch as hematuria seems to be the dominant danger signal this should be broadly stressed in public cancer-campaign literature. Patients with blood in the urine should know of the danger of delay and report it to the physician. The physician should proceed at once to identify the source of the bleeding. Even if this could be done in one hundred per cent of the cases there would still remain many late diagnoses. Roentgen examination and urologic investigation constitute our most reliable diagnostic regimen at the present time. We are in great need of measures to promote earlier diagnosis. Radiation seems advisable preceding as well as following operation. Follow-ups in the cases reported revealed that only one patient had survived five years postoperatively. A rare case of Wilms tumor in an adult is included in this report.

MATERIAL URGE VERSUS MATERNAL URGE

Not so many years ago, a childless woman was looked down on and pitied by her husband, her friends and neighbors. Then as time passed, the pendulum swung to the opposite extreme. This complete change of attitude is illustrated by the remark made by a woman reporter who came to our office at the Maternity Center Association just before the war. Said she: "My editor sent me for a story about maternity, but I can't see for the life of me why people want to have children today. Only morons are having babies."

Then the war came. A baby suddenly became important to millions of young people who hadn't thought much about having children up to that moment. Husbands and wives wanted a living symbol of their love even though they were separated by the oceans of half the globe. They wanted a tie to tomorrow—something of themselves, the value of which was not figured in cash. The birth rate skyrocketed. It was fashionable again to have babies.

Now the war is over. The impelling wartime reasons for having babies have vanished, and things that cash can buy become important again. People are settling down again to the habits of peacetime living and thinking of those shiny new cars, radios, television sets, refrigerators and the countless other expensive gadgets that have been promised us in our postwar society.

Will a baby continue to be a living symbol of the love of husband and wife for each other, or will a baby become an expensive little nuisance who keeps mother and father from buying that new television set? What is the new attitude going to be about babies? That remains to be seen. We will have to wait and see what the majority of the GIs want when they get home; what the new generation of young people, who were not old enough to go to war, will want when they get married.

That attitude will be set in our next generation of parents by what they have learned about the relationship of babies to their own married happiness. One favorable fact is that young people of this generation have not been content with the stork legend, or the doctor's bag. They have wanted to know the facts—and even if those facts were not provided in their school and college courses, at home or at church—they had the initiative to find out what they could, to put pressure on their teachers and their parents. If they succeed in arriving at a sound attitude about babies and family living, the credit is theirs and theirs alone for theirs is the generation which is causing a breakdown in the centuries old taboos and euphemisms.—*Maternity Briefs,* February, 1946.

CLINICAL-PATHOLOGICAL CONFERENCE

DIPHTHERIA: A REPORT OF SIX DEATHS

HAROLD H. JOFFE, M.D., and ARTHUR H. WELLS, M.D.

Dr A. H. Wells: The several fundamental lessons to be gain by a careful analysis of the following six deaths from diphtheria are mainly the result of many years of inexperience with the vicious nature of this disease. We wish to present a brief clinical and necropsy review of each case with a discussion of this group and a review of some salient features of the general subject of diphtheria.

Case Reports

Case 1.—This fifty-one-year-old white lumberjack was admitted to the hospital thirty-four hours before his death. He complained of a marked difficulty in swallowing and hoarseness, which had come on gradually during the past three days. At the time of admission, he was not even able to swallow water. There was also some difficulty with inspiration, and he had to breathe entirely through his mouth. His temperature was 102°F. and he did not feel very ill at any time. Physical examination revealed a thick gray-white membrane which covered the entire pharynx, including the soft palate, the nasal pharynx, laryngeal pharynx and, possibly, the larynx. However, the swelling precluded looking into the larynx. The examination was otherwise essentially negative. A smear from the pharynx revealed numerous Vincent's angina organisms and rare diphtheroid bacilli. Cultures on Loeffler's media were reported eighteen hours after admission, as containing morphologically and tinctorially typical diphtheria bacilli. These were later proved virulent by guinea pig tests. About thirty hours after being seen by the physician in his office and ten hours after the bacteriological recognition of the disease, the patient was given 30,000 units of diphtheria antitoxin. During his period in the hospital he was constantly cyanotic, more than would be accounted for by the apparent respiratory difficulty present. He managed to phonate some, and he was constantly coughing up a great deal of muco-purulent matter. The cyanosis was thought to be due to sulfadiazine therapy. During his last four hours he became quite cyanotic and his respirations were labored. His pulse reached 112, and respirations 46, during this period. After his death, morphologically typical diphtheria bacilli were found in the original throat smear.

The necropsy reveals an extensive swelling and thick diphtheritic membrane covering the entire larynx (Fig. 1) with almost complete obstruction of the air passage in the larynx, most severe at the vocal cords. There were mild gross and histologic evidences of toxic changes in the myocardium, liver, spleen and kidneys. Otherwise, the examination was essentially negative. It was concluded that the death was due to asphyxia.

Case 2.—This forty-year-old warehouse worker was first seen in his physician's office fifty-two hours before his death. At that time there was a thick, loosely attached membrane over the oral pharynx and tonsils. Soft tissues in the area of the membrane were swollen, leading to the clinical diagnosis of quinsy. An attempt to release pus from the swollen area by the insertion of forceps was made. There was also some swelling below the angles of the jaw on the same (left) side of the neck. About ten hours before death he was admitted to the hospital coughing bloody sputum and suffering from severe pain in his throat and some pain in the chest. Two hours later a culture was taken from the throat. Besides the areas described, the uvula and soft palate were also covered by a thick grayish membrane which bled easily. There were many coarse râles in both lungs. He was given penicillin and morphine. One half hour before death his color was considered good, but his pulse was weak. Fifteen minutes before death, he became severely cyanotic, his respirations were quiet and regular, and his pulse was very weak. Diphtheria antitoxin was withheld pending a report on cultures from the pharynx.

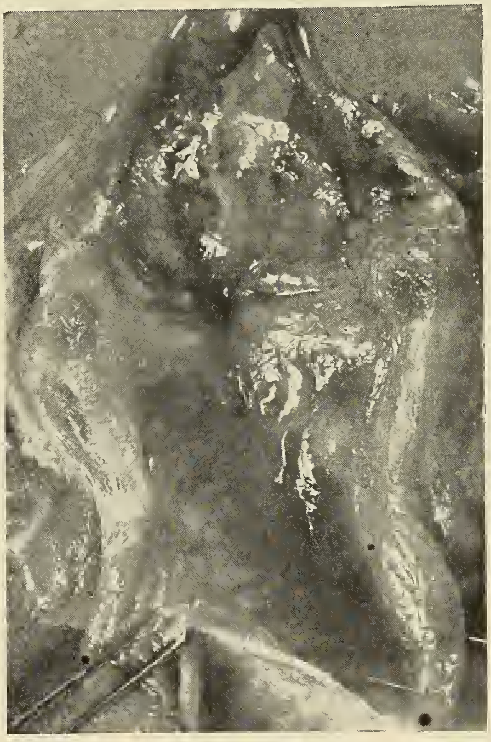

Fig. 1. Opened larynx with severe injection, swelling and diphtheritic membrane, the latter lifted by forcepts.

The necrosy revealed an extensive diphtheritic membrane extending down from the pharynx through the larynx, trachea, and major bronchi and, in places, into the smaller bronchi. The membrane and swelling in the larynx had caused almost a complete closure of the air passages, while the membrane and swelling in the smaller bronchi undoubtedly greatly hampered the exchange of air in the lungs. Death was due to asphyxia. Toxic changes in the myocardium, liver, spleen and kidneys were relatively mild.

Case 3.—A seven-year-old boy was first admitted to the hospital forty days before his death. He became sick seven days before admission, with general malaise, anorexia, and feverishness, associated with a sore throat and later a swelling in the lateral aspects of the neck. There was continuous fever and some coughing. A great deal of swelling of the tonsils, a marked fetor oris and whitish-gray adherent membrane over the oral pharynx, soft palate, and uvula, were noted. The child was considered very "toxic." There was a bloody

---

From the Department of Pathology—St. Luke's Hospital, Duluth, Arthur H. Wells, M.D., Pathologist.

drainage from the nose and some difficulty in swallowing. His temperature was 101°F., pulse 95, and respirations 22 per minute. He was given 60,000 units of diphtheria antitoxin immediately, along with supportive measures and penicillin. His white blood count was 17,300, hemoglobin 15 grams, and the differential count was essentially normal. There was 3 plus albumin in the urine. Throat cultures revealed diphtheria bacilli and for several days his general condition improved and he was finally discharged a month after entrance into the hospital, with some remaining difficulty in swallowing, partial palatine paralysis, nasal twang to his voice and some regurgitation of fluids through his nose. He was again admitted five days before his death, very dehydrated, acutely ill, having difficulty in swallowing and difficulty in breathing. His temperature was 101.6° F., respirations 24, and pulse 120 per minute. There was no voluntary movement of the uvula. Phonation was difficult. Some questionable dullness in the right lower lobe area of the lung and coarse râles throughout the lungs were found. His white blood cell count was 8,400 with 78 per cent neutrophiles; his hemoglobin was 12.5 grams; there was 2 plus albumin in his urine. An x-ray of the lungs led to the conclusion of pneumonia with associated atelectasis in the medial portion of the right lung. Although his temperature gradually returned to normal, his pulse remained high. He was given oxygen for his cyanosis. His condition improved considerably, so that he could breathe freely and get along without oxygen until, suddenly, one-half hour before his death, his breathing became more labored. There was increase in cyanosis without apparent obstruction to inspiration. Involuntary urination was noted, and he suddenly stopped breathing.

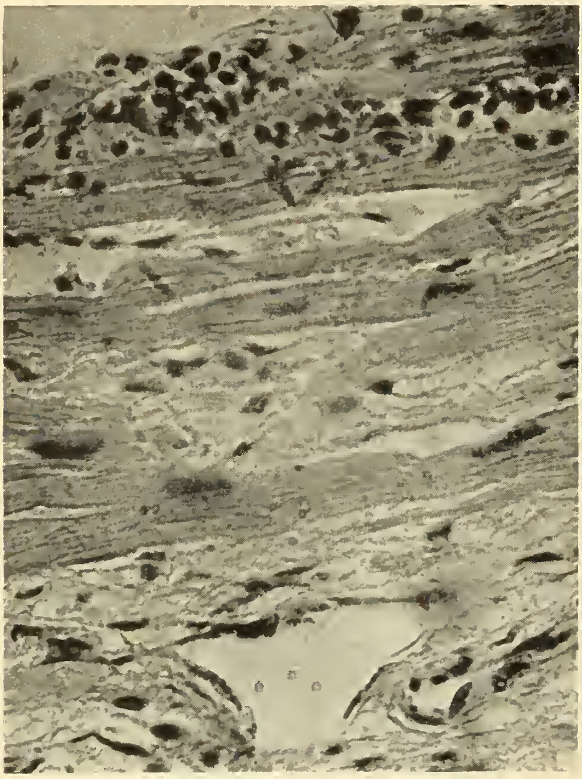

Fig. 2. Myocarditis with focal leukocytic infiltration, toxic degeneration of muscle fibers, swelling and hyperchromatic staining of nuclei and interstitial edema.

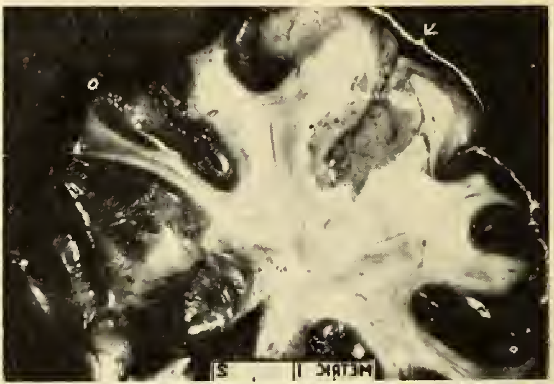

Fig. 3. Focal area of necrosis of cortex.

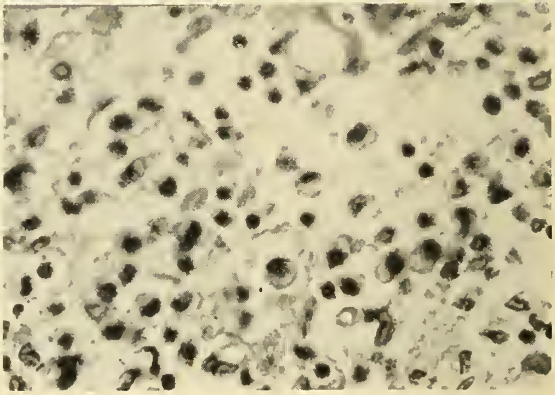

Fig. 4. New capillaries, fibrous connective tissue and many "scavenger" cells.

The necropsy revealed an unusually firm and remarkably pale myocardium which, on microscopic examination, had a diffuse myocarditis characterized by a generalized swelling and edema throughout the interstitial tissue with slight diffuse fibroblastic proliferation. There was also a lymphocytic and monocytic patchy infiltration with occasional neutrophiles, generally located about degenerated cardiac muscle fibers (Fig. 2). There was no Zinker's degeneration. A most remarkable area (3x6 c.m.) of apparent necrosis with extreme pallor (Fig. 3) confined to the cortical tissue just posterior to Broca's area on the left side, was found in the brain. Histologically (Fig. 4), the cortical nerve cells had completely disappeared from the involved region and was replaced by recently formed capillaries, loose connective tissue, many monocytic scavenger cells, and occasional lymphocytes. A third finding was an approximate two-thirds atelectasis of the lungs, associated with a mild, patchy, terminal bronchopneumonia. It was concluded that the patient had died, primarily, because of a combination of his diphtheritic myocarditis and pulmonary atelectasis of undetermined cause. The diphtheria infection itself had long been cured.

Case 4.—This six-year-old girl was admitted to the hospital 18.5 hours before her death with a sore throat and headache of four days' duration. She apparently had been coughing for about two weeks but had not been very ill. Four other children in the same family had sore throats; three were attending school. Her pulse was 150; and respirations 30 per minute; temperature was 101.6°F. She appeared acutely ill, with a flushed face, obviously difficult breathing, nasal congestion and watery discharge from the nostrils. Oral pharynx and tonsils were covered by a thick grayish adherent membrane. There was severe fetor oris. The lateral aspect of the neck and cervical glands were swollen. There were stridulous râles in the lungs, particularly at the right base. She was immediately given 60,000 units of diphtheria antitoxin. Penicillin, sulfadiazine, and supportive measures were used. She had received antidiphtheria immunization by a three-injection method two years previously. Throat cultures revealed diphtheria bacilli. Two hours after admission she was having considerable respiratory difficulty and was quite cyanotic. A tracheotomy resulted in immediate relief. She was very restless and did not sleep more than half an hour during the entire night. Her temperature reached 106°F. There was much exudate coughed through the tracheotomy tube. She was breathing satisfactorily one half hour before her death, and became cyanotic with increasing rapidity of respirations and pulse five minutes before death. Her pulse had gradually risen while in the hospital from 130 to 168 per minute and her temperature from 101.6°F. to 106°F.

The necropsy led to the conclusion that this girl died as a result of "toxemia" mainly through its effect on her heart muscle. However, there was no inflammatory change in the heart. There was considerable swelling and membrane formation in the larynx with rather severe obstruction. No obstruction or membrane formation was found below the tracheotomy opening. There was a mild bronchopneumonia.

Case 5.—This four-year-old boy was admitted to the hospital two hours before his death. The child's father had recently returned from the European theatre of the war. His parents explained that he had had redness and swelling of his ear for five days. During this period he had coughed some and complained of a sore throat. He had not been able to eat or drink, apparently because he could not swallow. A physician had been called but was too busy to make a house call. Another physician visited two days before the child's death and made a diagnosis of mumps prescribing cold packs to the neck. Physical examination revealed an acutely ill child in extremis. He was cyanotic. His temperature was 102.4° F. and pulse 96. There was much wheezing over the trachea and bronchi, labored inspiration, dry, cracked tongue and lips, foul and fetid odor of the breath. Inspiratory effort was pronounced and there was a dirty, grayish, adherent, thick membrane over the tonsils, uvula and pharynx. There was swelling below the angles of the jaw and the lateral aspects of the neck (Fig. 5). There was none in front of the ears in the parotid area. He was given 30,000 units of penicillin intravenously immediately after admission and an hour and fifteen minutes later he received 20,000 units of diphtheria antitoxin intramuscularly. Oxygen therapy and other supportive measures were instituted. His inspiration continued labored and was apparently partially obstructed. His pulse became weak and rapid. He became much weaker. His pupils did not react to light; cyanosis became more marked; respirations more forced; and the pulse was unobtainable, shortly before respirations ceased.

The necropsy revealed only mild diphtheritic involvement of the upper portion of the larynx without interference with its lumen. Various internal organs had moderate toxic changes, seen both grossly and microscopically. Death was considered to be the result of "toxemia," particularly as it affected the myocardium.

Case 6.—This nine-year-old boy, a brother of the child in Case 5, was admitted on the same day with his brother. He died six days later. He had been sick for two and one-half days before admission with a sore throat and headache. There had also been severe malaise, anorexia, dysphagia, nasal discharge, and some apparent respiratory difficulty. His temperature was 100.8°F., pulse 88, and respirations 28 per minute. He was considered severely and acutely ill. There was an incomplete, dirty, purulent membrane over the oral pharynx, uvula and tonsils. His breath was very foul. The lateral aspects of the neck below the angles of the jaw were swollen. He was given 40,000 units of diphtheria antitoxin intravenously immediately along with penicillin and other therapy, the 40,000 units of antitoxin being repeated the following day and again on the third hospital day. He seemed to show gradual improvement during the fourth and fifth hospital days. On the day before death, respiratory obstruction developed, and a tracheotomy was performed. He breathed much easier and cyanosis decreased. He coughed up considerable exudate. He had been given over 6,000 c.c. of parenteral salt solution during five days. The inaccurately measured daily output during this period totalled 1,000 c.c. Blood pressure and blood urea measurements were not performed.

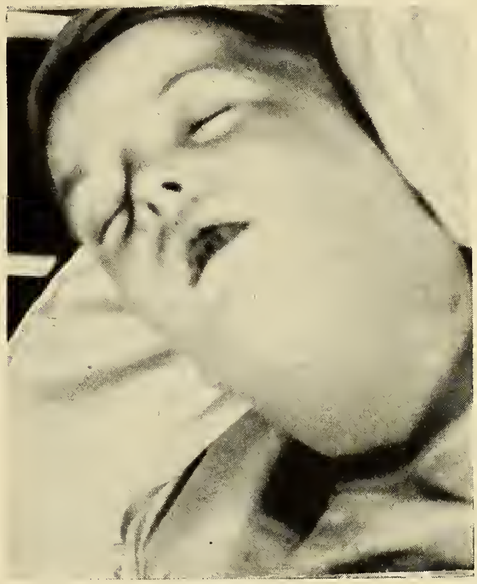

Fig. 5. "Bull neck" due to diphtheria.

The necropsy revealed approximately 75 per cent atelectasis of both lungs and a grade IV pulmonary edema. There was practically no aerated lung tissue remaining. There was, in addition, a moderate edema throughout the subcutaneous tissues and the soft tissues of both thorax and abdomen. The mechanism of death might include poor aeration of the lungs due to (1) respiratory muscle weakness, with resultant severe atelectasis of lungs and (2) excessive sodium chloride intake for this acutely ill child, with resultant pulmonary edema and general anarsarca.

Discussion

Among the more important lessons to be learned in this small group are:

1. Suspect diphtheria with every membranous pharyngitis.

2. Do not let large numbers of Vincent's angina organisms in the direct smear interfere with the careful exclusion of diphtheria bacilli.

3. Treat for diphtheria without waiting for laboratory culture reports if the case looks very suggestive.

4. The patient with diphtheria need not seem very ill, even within a short period before death.

5. The diphtheria patient has a good chance of developing respiratory tract obstruction and must be watched closely for it.

6. This obstruction may exist without the usual sound effects.

7. The measurement of vital capacity may be indicated in certain cyanotic patients.

8. Laryngoscopic examination and aspirations should be used freely.

9. It requires only a few minutes to cause death by asphyxia in diphtheria.

10. In malignant diphtheria, larger dosages of antitoxin are indicated.

11. Precious time may be lost between the time of diagnosis and the institution of therapy.

12. Daily parenteral saline exceeding 700 c.c. in adults and less in children may cause death by pulmonary edema, in these acutely ill patients. Give glucose solutions when parenteral water therapy is indicated.

13. A "bullneck" of diphtheria is not mumps, but a serious prognostic sign.

14. Not all peritonsillar swellings are due to quinsy.

15. The postdiphtheritic patient with paralysis must be watched carefully for a long period in the hospital.

16. Diphtheria immunization alone does not always protect against diphtheria.

17. Expect and treat diphtheria early, in diphtheria contacts.

Dr. H. H. Joffe: The following discussion of diphtheria is not an original investigation, but rather a brief résumé of some of the literature on the subject, in which an attempt had been made to clarify some of the puzzling clinical variations and pathogenicity of the disease.

Bacteriology

There are numerous Gram positive rods with tendency to club and pointed forms which are widely distributed in nature and as a rule are non-pathogenic. This group of organisms are designated "the diphtheroid group of bacteria" and are morphologically closely related to the one species Corynebacterium diphtheriae called a "true diphtheria organism."[9] This organism in contradistinction to the diphtheroid group is pathogenic by virture of its toxin and the cause of clinical diphtheria. Many diphtheroids are found in the human throat and the contamination of cultures increases the difficulty in differentiating them on smear from the true diphtheria organism. In this connection, it was of interest to learn that the State Department of Health Laboratories in Minnesota[6] do not routinely perform virulence tests on the organisms which are morphologically diphtheria bacilli in cultures from patients clinically diagnosed diphtheria unless the organisms persist in the nose and throat cultures for a period of at least forty days following the first symptoms. The inaccuracy of morphologic diagnosis alone is illustrated in the results of virulence tests at the State Laboratory during 1945. Of 892 such tests run on morphologically typical or suggestive bacilli from a variety of sources, only 382 were proved virulent.

The difference in the colony appearance on tellurite chocolate agar and the comparative variation in the clinical picture of the disease resulted in the recognition of three types:[2] mitis, intermedius and gravis; although a small percentage of strains do not closely resemble any of these types. The mitis strain is usually associated with clinically mild diphtheria and death, if it does occur, is mostly in infants and is due to either obstructive phenomena or pneumonic complications or both. The intermedius strain closely resembles the gravis type in the clinical symptoms produced, but disappears more rapidly in convalescence and does not have the tendency towards epidemic spread. The gravis type has a greater pathogenicity, deeper penetrating power of tissues and greater epidemic potency.

The description of the malignant diptheria is not new and can be found in the writing of Hippocrates and those of the 2nd century A.D. Many epidemics have occurred in various parts of the world with[2] 1,000,000 cases reported on the European continent, exclusive of Russia, in 1943 with a mortality rate of not less than 5 per cent. Diphtheria reached epidemic proportions during this present war and was the[10] leading epidemic disease on the European continent as a cause of both morbidity and mortality. The rate per 100,000 of population, rose considerably in many of the European countries between 1939 and 1943:

Rate per 100,000 of population[2]	1939	1943
France	35.9	118.7
Netherlands	16.6	638.9
Norway	1.8	752.8
Germany	180.9	287.1
Britain	114	84

It can be assumed that the marked increase in the incidence of diphtheria was initiated by war conditions. In the case of Britain it can be assumed that the strict vigilance of sanitary conditions may be one of the causes to account for the decrease in the incidence.

In this country, a small epidemic occurred at Belair, Md., in 1936, and a severe outbreak in Halifax, Nova Scotia in 1941. A malignant type has appeared in Germany and has cast some doubt as to the efficacy of the supposedly satisfactory and conventional method of management. In the Halifax epidemic[10] 69.2 per cent of cases occurred in the age group over fifteen years. As high as 80 per cent of the adults in the general population were susceptible as measured by the Shick test.

It seems probable that the numerous severe outbreaks of diphtheria described in Europe, which were refractory to serum therapy were due to the gravis type of diphtheria bacilli. This refractory character of the diphtheria stimulated many investigations. Anderson and associates[12] at Leeds, England, suggested a casual relationship between the gravis type and malignant diphtheria. Although this received some confirmation, it was noted that in other areas numerous strains which were culturally typical of the gravis type were avirulent as shown by ordinary laboratory tests.[3]

In order to explain the factors involved in the production of malignant diphtheria, the following equation has been suggested:

$$\frac{\text{Toxigenicity of C. diphtheria} + X}{\text{Host resistance}} = \text{Malignant diphtheria}^{3}$$

The possible factors which could be represented by X are: (1) the symbiotic existence of hemolytic streptococci; (2) the occurrence of an alteration in the strains of C. diphtheriae prevalent in an area which would cause them to acquire a greater pathogenicity; (3) unknown toxic substance other than that of C. diphtheriae; (4) individual immunological response to infection. There is no evidence to prove that change of virulence is likely to occur and the possibility of unknown toxic substances must remain as conjectures until further proof is available.[3] The X factor is best expressed by Park, Williams and Krumwiede. They state "when other pathogenic bacteria are associated with diphtheria bacilli they mutually assist one another in their attacks on the mucous membrane, the streptococci being particularly active in this respect, often opening the way for the invasion of the diphtheria bacillus into the deeper tissues or supplying needed conditions for the development of its toxin. As these septic infections due to the pyogenic cocci are in no way influenced by the diphtheria antitoxin, they frequently are the cause of the fatal termination."[3]

The Minnesota Department of Health statistics for the last decade[6] revealed 40 per cent of the diphtheria was in patients over ten years. The morbidity and mortality from the disease had been falling steadily until 1943, since when there has been a gradual rise.

Clinical Recognition

The salient features of malignant diphtheria may be summarized:[12]

1. The symptoms are sudden in onset and very severe.
2. There is frequently an associated cervical cellulitis, giving rise to the "bull neck" appearance.
3. Due to the intense swelling of the pharyngeal parts, respiration is of a snoring type.
4. Thick membrane covers the tonsils, anterior pillars and uvula and at times extends onto the mucous membrane of the hard palate and cheeks.
5. Tonsils may be so swollen as to compress the uvula.
6. Membranes are grayish in color or even darker with blackish hue due to hemorrhage following necrosis of the underlying tissue with development of gangrenous areas.
7. Involvement of the nasal mucous membrane is common with nasolabial excoriations.
8. Temperature is generally higher than the average case and runs a septic course.
9. Evidence of circulatory failure appears early.

In a report of eighteen cases on a United States Naval Hospital ship, ten were originally diagnosed as tonsillitis at the onset of their illness, and one case was mistaken for a peritonsillar abscess, which was incised.[8]

Treatment

The efficacy of the prophylactic use of standard toxoid and alum-precipitated toxoid is generally accepted. The present increase in the frequency of diphtheria and the possible influx of more virulent strains from overseas necessitates a greater use of "booster" or activating doses of toxoid among all age groups of our present population. The Minnesota Department of Health recommends that all children who have been immunized early in childhood should receive booster doses of toxoid before they enter school. In a recent report, Karelitz[5] found 28.6 per cent of 1,283 individuals in the armed forces were Shick positive. These received a booster dose of toxoid, and within four months a high percentage became Shick negative.

Beckman[1] demonstrated a direct relationship between the mortality and a delay in the administration of antitoxin, from an expected mortality of 1.5 per cent on the first day of illness to 14.92 per cent on the fifth day. Norris[8], in an epidemic of eighteen cases, found that where the antitoxin was given within three days of the onset no paralysis developed, whereas, in the cases treated after this period the antitoxin did not prevent paralysis. The more serious types of diphtheria should undoubtedly receive higher dosages of antitoxin. According to Weinstein[14], the degree of "bull neck" bears a direct ratio to the degree of toxication, and doses as great as 160,000 units of antitoxin are of no avail once the condition has fully developed. In a group of thirty-six deaths from diphtheria, Togasaki[13] reported twenty-two had required tracheotomy. Bronchopneumonia and toxic myocarditis headed the list of complications.

Clinical and experimental[7,12] proof has been submitted that the use of sulfonamides and penicillin do not affect B. diphtheriae directly. However, these drugs may be very efficacious in their prophylactic and therapeutic effect upon streptococci and other organisms, which may well have a symbiotic relationship with the diphtheria organism.

Conclusion

It is obvious that the low incidence of diphtheria in this community has led to a feeling of security and a depreciation of ability to recognize and treat this disease. There undoubtedly has developed large numbers of individuals, particularly among adults, who are now susceptible to diphtheria and may become the fuel for an epidemic of a malignant type of diphtheria, possibly brought to this country by carriers among our armed forces. The diagnostic and therapeutic lessons gained from a study of the reported six cases of diphtheria have been summarized under Discussion. Some of the recent trends in the literature concerning epidemiology, malignant diphtheria, practical bacteriology, activating or "booster shots," and the importance of early antitoxin therapy, are briefly reviewed from the literature.

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from March issue)

Physicians in Fillmore County

Physicians were in Fillmore County, of course, as early as 1852, although dispensers of propaganda in encouragement of colonization gave them scant recognition. From the beginning, Minnesota, first a territory and, in 1858, a state, was proclaimed to yield to no region in the world in point of salubrity of climate. In the fifties and sixties, when the state government was actively encouraging immigration, newspapers throughout Fillmore County, as elsewhere in the state, published comments like this: "Hardly a day passes without our seeing numerous wagons loaded with men, women and children traveling along our roads. Many from Iowa, Illinois, Indiana and other states. The healthy air of Minnesota will take off that sickly aguish look of most of them . . . let them come! There is room for all—and more too." As to medical practitioners, J. W. Bishop, in his *History of Fillmore County*, of 1858, said, in part: "Thoroughly qualified physicians walk among us 'harmless as doves' in this horribly healthy country!" In those early years the general idea was that the physician's chief usefulness lay in surgical cases and in obstetrical cases (complicated) and in attending such patients as might contract chickenpox, measles, smallpox or diphtheria.

The need and opportunity for physicians soon were recognized, however, and although statistics have not been available for comparison of Fillmore County with other counties in number of physicians, it seems probable that with the possible exception of Ramsey and Hennepin Counties, which had as drawing cards St. Paul and St. Anthony (Minneapolis) at the head of navigation on the Mississippi River, this large southern County of Fillmore, lying in one of the main paths of immigration, received in the nineteenth century as large a representation of medical practitioners as any other county in the state. Certainly there is record, scant or full, of many physicians, permanent or temporary. Scanning of such old newspapers of various years as have been available to the writer has yielded, in addition to those learned from other sources, the names of sundry practitioners who remained in the county probably a few months or a year or two and were heard of no more. If such record is indicative, there must have been, over a period of decades, many more than are mentioned herein of this unsettled type, who were frankly itinerant or who with some appearance of stability moved from town to town in the county before going on into other sections of the state or the country.

Among the total number of physicians, especially of those who came in the fifties, sixties, seventies, and into the early eighties, there undoubtedly were men of little knowledge and less training who had no legitimate excuse to call themselves "doctors." An occasional veterinarian found it expedient to treat human patients as well as domestic animals and poultry; in fact, physicians occasionally found it well to treat domestic animals. There were vendors of patent medicines, hydrotherapists, bone-setters, herb doctors (botanic and physiomedical schools were the forerunners of eclectic medical institutions, although "herb doctors" probably had not been within their portals). There were honest representatives of the preceptor system alone and of the preceptor system combined with instruction or lectures at medical colleges: eclectic, homeopathic and regular (in the early period *allopathic* was used often to indicate the regular system of medicine and surgery), of one or the other of which many were graduates. Some of the finest practitioners came from universities and medical schools of Norway, Sweden, Holland, Germany and Britain and exerted a constructive influence on the growth of medical practice in the new land; some of the worst purported to come from foreign schools. There were many representatives of the various eclectic colleges of Cincinnati and Chicago and of the homeopathic schools, particularly the Hahnemann Medical College of Chicago in its different alliances. Worthy of mention, there were graduates of some of the smaller medical schools of New England and neighboring states which supplied the Middle West with perhaps her soundest medical pioneers. Among these institutions, in Vermont, were the University of Vermont and the Castleton Medical College (Vermont Academy of Medicine); in Maine, the Medical School of the University of Maine and Bowdoin Medical College; in New York, the College of Physicians of the Western District of New York, at Fairfield, the Geneva Medical College, the Albany Medical College and the University of Buffalo Medical College. These schools at least tried to set standards high and to insist on good preliminary education. There were a few men from the greater medical schools of the Atlantic seaboard and from McGill University in Montreal. Graduates came also from the schools of the Middle West: the Miami Medical College (later the Medical College of Ohio), Rush Medical College, the Chicago Medical College (later the Medical Department of Northwestern University), the Medical School of the University of Michigan, the College of Physicians and Surgeons of Keokuk (Iowa), and the Missouri Medical College, to name only a few. Beginning in the eighties came men from the schools of Minnesota: the Minnesota College Hospital (later the Minnesota Hospital College), the Minneapolis College of Physicians, the Minnesota Homeopathic Medical College and the St. Paul Medical College, and, finally and chiefly, the Medical Department of the University of Minnesota, after the establishment of which medical education became a function of the state. As told by many writers on medical history in Minnesota, two of the early medical schools that had functioned in Minneapolis and St. Paul (the Minnesota Hospital College and the St. Paul Medical College) joined in forming the medical department, first known as The College of Medicine and Surgery, of the university; others subsequently united with the university school; others passed out of existence.

A constantly recurring pattern among the physicians who came in the earlier decades of this second half of the nineteenth century was the birth and education abroad or in the eastern United States and the trek to the Middle West broken into stages by residence of years, perhaps, in one or more places en route. Occasional mention is seen of practitioners among the earliest of the pioneer physicians who were of such decided personality and opinion that they antagonized their patients and thereby lost in material benefit, but whatever their temperaments they all must have been strong characters, because no weakling would have chosen to break trail in a new country of crude living conditions that still was not free from threat of attack by Indians.

Because the physician's relationships were with settlers in large communities, in townships rather than in villages alone, the townships of Fillmore County are named here, from east to west in four tiers from south to north. In the first and southernmost tier, bordering on Iowa, are Newburg, Canton (originally Elyria), Harmony, Bristol, York and Beaver Townships; in the second, Preble, Amherst, Preston, Carimona, Forestville and Bloomfield; in the third, Norway, Holt (Norway and Holt together once were Douglas), Carrolton, Fountain, Fillmore and Spring Valley; and in the fourth and northernmost tier, Rushford, Arendahl (early a part of Rushford), Pilot Mound, Chatfield, Jordan and Sumner.

It is difficult to say who was the first physician* so-called, in Fillmore County, but of the established practitioners of unquestionably high repute, probably the first was Dr. William C. Pickett, in 1852, one of the sons of a family who had pioneered from New York to Indiana some years earlier. Dr. Pickett shortly returned with his traveling companions to Indiana and in the following summer came back to Fillmore County with a group of four Pickett families and was the moving spirit in the founding of Carimona Village in Carimona Township. The next few who came, between 1853 and 1858, were: Horace W. Pickett and Henry L. Wilson to Carimona; Nelson W. Allen, Refine W. Twitchell, Augustus H. Trow, D. N. Morse, Isaac S. Cole and Luke Miller, to Chatfield, Chatfield Township; Erastus Belden and Wallace P. Belden, father and son, to Hamilton, Sumner Township; J. Early, H. Gilbert and William H. Dean and, possibly, T. E. Loop, to Spring Valley, Spring Valley Township; Lafayette Redmon and John W. Crees to Preston, Preston Township; H. Curtis to Fillmore, Fillmore Township; Robert A. Sturgeon and Thomas Little to Elliota and James M. Wheat to Lenora, both villages in Canton Township.

The roster of physicians of Fillmore County which follows is submitted with full consciousness of its obvious defects. The men are named alphabetically in the known or estimated decades of their arrival, with the first known village and township of the practice of each. It should be stated that some of these men were born in the county and spent their entire lives there with the exception of years given to medical study elsewhere. Others came there as children of pioneer parents, went away for their medical schooling and returned to practice. Still others, who came as physicians from the outside, spent a professional lifetime in one place. Many, of all groups, changed locations within the county once or several times, and many others resided in the county a relatively short time. Of some the exact date of arrival is known, of others it can be said only that they arrived in the fifties, or in the sixties before 1866, for instance, or that they may have been long in the region but not in Fillmore County until the seventies or eighties or some other period. In the sketches these facts will be made clear whenever possible. And, although the statement is not truly germane, it may be said that other men, like John C. Nelson, later of St. Paul, who came under the influence of the pioneer physicians and who received inspiration to study medicine while working in the early well-known drugstores of Fillmore County, did not return to the county after qualifying as physicians but achieved notable medical careers elsewhere.

---

*Although individual physicians are mentioned in this narrative, by decades of arrival and in connection with the organization and development of medical practice in the county, biographical detail is reserved for the series of sketches which are appended and which to some extent carry the thread of the story, showing forth mannrs, customs and events.

ROSTER OF PHYSICIANS IN ORDER OF ARRIVAL BY DECADES†

1852-1899

Name	Village	Township
1852-1859		
Allen, Nelson W.	Chatfield	Chatfield
Belden, Erastus	Hamilton	Sumner
Belden, Wallace P.	Hamilton	Sumner
Cole, Isaac S.	Chatfield	Chatfield
Coleman, W. F.	Chatfield	Chatfield
Crees, John F.	Preston	Preston
Curtis, H.	Fillmore	Fillmore
Dean, William Henry	Spring Valley	Spring Valley
Early, J.	Spring Valley	Spring Valley

Lommen, Andreas Pederson	Mabel	Newburg
MacDonald, Alexander*	Chatfield	Chatfield
Meidell, Roy A. O.		

---

*The name of Dr. Alexander MacDonald is included because, although he was not in Fillmore County until 1901, he had been in southern Minnesota since 1883, and he has been (1944) in Chatfield forty-three years.

Nass, Hildus Augustinus O.	Mabel	Newburg
Onsgard, Christen K.	Rushford	Rushford
Ray, Charles Wilbur	Canton	Canton
Richardson, Walter Earl	Preston	Preston
Shipman, Louis Dwight	Preston	Preston
Thompson, Edward R.	Harmony	Harmony
Utley, John Darwin	Spring Valley	Spring Valley
Walker, Charles Carroll	Chatfield	Chatfield

Intercounty and Interstate Practice.—In all decades physicians extended their practice into several townships and into neighboring counties and even into neighboring states. Fillmore County practitioners were called into all contiguous counties in Minnesota and into Howard and Winnesheik Counties of Iowa, and men of those counties were in turn known in Fillmore County. Notably, Dr. G. M. Alsdurf, an eclectic physician and surgeon, an early arrival at Le Roy, Mower County, and a few years later at Spring Valley, Fillmore County, began at once to treat the sick of a widespread territory; "happening to strike the place (Le Roy) just in one of those terrible scourges, an epidemic of diphtheria, he had business immediately and went right into an extensive practice, in the counties of Mower and Fillmore, in Minnesota, and Howard and Mitchell, Iowa." John Lewis Martin, physician and preacher, chiefly of Dodge County, but also of Olmsted, Jackson and Mower Counties, is said to have practiced in Fillmore County. He has been described as a small, wiry, bewhiskered man, dignified and respected, who rode on horseback to make his professional calls and to relieve in the pulpits of his brother clergymen. Of a much later generation, Henry S. Plummer, native of Fillmore County, later of Mower County and Olmsted County, in his early years as a physician practiced from Mower County with his father, Dr. Albert Plummer (Fillmore County, 1869-1893; Mower County, 1893-1911), into Fillmore and Olmsted Counties. From Fremont, Winona County, William Shaw Morrison, a pioneer physician for many years maintained an office in Chatfield also and on two days a week saw patients there.

From various other counties in Minnesota in the eighties and nineties the following physicians filed their licenses in Fillmore County, although record has not been noted that they ever resided there: John T. Billington, Yellow Medicine County, 1887; N. D. Satterlee, Jackson County, 1888; Halfdan Slippern, Hennepin County, 1897; George B. Hamline in 1898 and John Edmund Doran in the same period; and Herman Russell, Olmsted County, in 1899.

From Iowa, Fordyce Worth, of Hesper, Winnesheik County, long practiced in the vicinity of Mabel, Newburg Township, and was licensed in Minnesota in 1887. Other Iowa physicians who were licensed to practice in Fillmore County were John W. Reed, Frank Fremne and Daniel M. Sage, in 1884, and Francis J. Ledbrook, in 1896, all of Howard County. From Wisconsin were registered Thomas Thorkelson, of Trempeleau County, in 1896, and George A. Morley, of Juneau County, in 1898.

In the series of biographical sketches to come, notes have been included on three of these men from outside Fillmore County, who no doubt were typical of many.

(To be continued in May issue)

President's Letter

EXCELLENT ANNUAL MEETING FORECAST

YOUR State Meeting this year is to be the acme of all state medical meetings, probably surpassing in variety and excellence all previous or other meetings except that of the American Medical Association. From scientific discussions to commercial exhibits, the meeting promises features worthy of the history-breaking attendance which seems assured.

That it is to be *your* meeting has been the primary objective of both the Executive Secretary and the Program Committee. Questionnaires were sent by the Executive Secretary to every military and civilian member of the Association. Essentially these asked only two questions: "What scientific subjects do you wish presented?" and "How can the State Meeting best be planned and arranged for your needs or desires?" From the response to these questions, the Program Committee and Executive Secretary designed and arranged the entire conclave. So, your needs, desires and requests were the nucleus from which the meeting was fashioned.

On the scientific program are to be found outstanding papers and lectures by leading authorities in the various fields, round table discussions conducted by one or more prominent clinicians, special sectional sessions with physicians of national renown as guest speakers, and actual demonstrations of the most up-to-date technics, procedures and methods. Subjects on the program of scientific lectures include: surgery of the gall bladder and pancreas, coronary disease, brucellosis, malaria and other tropical diseases, sulfonamides, penicillin and streptomycin, surgery of thrombophlebitis and embolism, obstetrical shock, third stage of labor, the Rh factor and transfusions, "punch" and suprapubic prostatectomy, endocrinology, intervertebral disc x-ray study, and a whole symposium on hospital subjects.

For round table luncheons such topics as the following have been arranged for full and free discussion by all present: thiouracil, allergy, burns, esophageal obstructions, amino acids, arthritis, anesthesia, varicose veins, gall-bladder surgery, dermatology, ulcerative colitis, rheumatic fever, tuberculosis and poliomyelitis. Here is a place to present your clinical problems for a wealth of consultative opinion.

Special sectional sessions of the Minnesota Academy of Ophthalmology and Otolaryngology, Minnesota-Dakota Orthopedic Club and the American College of Chest Physicians will be held one morning for each group. And on Monday afternoon can be heard the Carman Lectureship in Radiology, while Tuesday afternoon will have a special pediatrics lecture by a nationally prominent pediatrician.

Ringworm of the scalp (tinea capitis), blood plasma and obstetric manikin demonstrations will be so arranged as to have one or another of the three each morning and afternoon. Besides these, special scientific exhibits or demonstrations have been requested from 31 agencies, groups or committees including several hospitals and sanatoria, various clinical committees, allied professional groups, veterinarians and pathologists.

Over and beyond this grand array of clinical and scientific information, commercial exhibits of every nature and description will accentuate the necessity for your attendance and participation. The newest drugs, pharmaceuticals, appliances, apparatus, equipment, methods, procedures technics, books, periodicals and literature will be on display in the greatest profusion in one of the largest commercial exhibitions yet seen.

You can use it for what it was planned, the most intensive and well-balanced of refresher courses. Whether specialist or general practitioner, it cannot miss your needs and fancy. So let's all make it the biggest and best medical meeting ever held in Minnesota.

Edwin J Simons

President, Minnesota State Medical Association

THE USE AND ABUSE OF PARENTERAL FLUIDS

VALUABLE as the administration of parenteral fluid may be, one can err seriously in giving too much fluid containing electrolytes to patients who need only glucose in water or in not giving fluid containing electrolytes to patients who need them.

The normal adult drinks 1500 c.c. or more of liquid daily. In addition he obtains about 1200 c.c. of liquid from his food. The moisture lost through insensible perspiration and expired air amounts to about 1200 c.c. so that the liquid obtained from food balances approximately that lost from the skin and lungs. The 1500 c.c. of liquid drunk during the day is necessary for proper kidney function in the elimination of salts and waste products of nitrogen metabolism. Fever, high environmental temperatures, and exertion even without sweating increase the loss from skin and lungs and consequently increase the fluid requirement.

If, for any reason, a normal amount of fluid cannot be taken by mouth, parenteral fluid is indicated. Following an operation for instance, when a patient is unable to eat or drink, he requires from 3000 to 4000 c.c. of parenteral fluid to prevent dehydration. All this should not be given in the form of physiological saline or lactate-Ringer's solution. Acutely ill patients and particularly postoperative surgical patients tolerate excess sodium chloride very poorly. Pulmonary edema, peripheral edema and oliguria can result from the use of too much saline solution in such patients. The normal daily intake of sodium chloride ranges from 4.0 to 10.0 Gm. so the administration of saline parenterally should be limited to 4.5 Gm. sodium chloride in each twenty-four hours unless there is an abnormal fluid loss by fistula, drainage, et cetera. It should be remembered that physiological saline solution contains 9.0 Gm. of sodium chloride per liter and lactate-Ringer's solution contains 6.0 Gm. of sodium chloride and 2.7 Gm. of sodium lactate per liter. Three liters of saline solution contain 27.0 Gm. of Sodium Chloride and the same volume of Ringer's solution contains 18.0 Gm. of sodium chloride and 8.1 Gm. of sodium lactate. It should be remembered too that plasma, amino acid solutions and blood contain sodium chloride and other sodium salts in appreciable amounts.

If gastric or duodenal suction has been instituted, there is need for additional parenteral fluid and sodium chloride to replace that lost through the suction. Fluids obtained from the stomach and duodenum contains approximately an equivalent of 5.0 Gm. of sodium chloride per liter. Fluids and sodium chloride lost by suction should be replaced. Determination of plasma chloride levels at intervals is essential if suction is continued for many days, for the above replacement rule represents minimal requirements.

There are many conditions which cause dehydration by the excessive loss of both water and electrolytes: copious vomiting from pyloric obstruction, intestinal obstruction or other causes; severe diarrhea; drainage from external biliary, pancreatic, and other fistulas; transudation or exudation of fluid from large denuded or burned areas; profuse sweating; diabetic acidosis with loss of fixed base combined with acetone bodies; and excessive loss of sodium chloride in the urine of patients with Addison's disease. Serious errors can be made by failing to supply adequate sodium chloride (or sodium chloride with sodium lactate or bicarbonate) in the appropriate instances. Each of the above causes of dehydration represents a special problem and cannot be discussed here, but it must be emphasized that these conditions must be recognized and treated properly.

In medical cases it is just as important to preserve electrolyte balance. If the kidney function is impaired to such an extent that the blood urea nitrogen and creatinine are increased, water is needed in larger volume than in normal individuals for the elimination of metabolic products. If the plasma chloride is normal or elevated in the presence of edema, sodium chloride in the diet or saline solution parenterally is contraindicated. Parenteral fluid in the form of glucose in distilled water may be given. Schemm has shown that in the presence of edema of nephritic or cardiac origin, fluid without salt and an acid ash diet will help reduce edema by their diuretic action. Saline solution will only aggravate the edema present and tend to produce pulmonary edema. Water should not be restricted even in the presence of edema but may be forced if the salt intake is restricted.

Edmund B. Flink, M.D.

STUDY OF CHILD HEALTH SERVICES

THE Council of the Minnesota State Medical Association at its recent meeting in Minneapolis approved a plan for conducting a Survey of Child Health Services throughout the state. In order that every physician in the state of Minnesota will be fully informed on the purpose and plan of this study, regular announcements regarding its various phases will be made from time to time through the office of the Minnesota State Medical Association. The action of the Council has been made public but a more detailed explanation for the physicians of the state is in order at this time.

The American Academy of Pediatrics, at the annual meeting in St. Louis in November, 1944, formulated a plan which is being carried out by a special committee under the direction of Dr. John P. Hubbard, who was a member of the Children's Hospital Staff in Boston until he entered the Medical Department of the Army. The organization of this survey has now been completed.

The reason for inaugurating this study arose from the realization that, if all children are to receive the care they need, systematic planning is necessary. It was felt that the responsibility for such planning should rest on the physicians themselves. Physicians know what constitutes good care; physicians for the most part provide this care and they are the ones who should develop and conduct such a program. However, in order to develop a plan, facts regarding the services available must be determined.

One purpose of the study is to stimulate groups and individuals to evaluate the existing facilities and to determine the needs within their own communities. Unless physicians undertake this task, others less qualified will, as has been indicated by proposed legislation now before Congress.

The content of the study falls into four categories:

1. Hospital facilities.
   Information on pediatric care will be sought from all hospitals: general, pediatric and maternity; convalescence homes; tuberculosis sanatoriums and so forth.
2. Community health services, public and private.
   Information will be sought regarding the extent and quality of child health conferences, school health services, child guidance clinics, immunization programs and public health nursing.
3. Distribution and qualifications of professional personnel and available services.
   Information will be requested from pediatricians, general practitioners and specialists who care for children. The availability of physicians and of procedures employed in medical care, such as transfusion, intravenous administration of fluids, artificial respiration, administration of oxygen and laboratory work, will be determined.
4. Pediatric education.
   A special committee will study the sixty-six medical schools throughout the country to determine the quantity and quality of pediatric teaching.

When the study has been completed, a report will be prepared which will be available to all who care to use it. It will be a collection of facts which may be used as a basis for sound recommendations for medical care.

Members of the American Academy of Pediatrics are committed to aid in this study of child health services.

Responsibility for the organization and inauguration of the study within each state was delegated to the state chairman of the Academy who, with the help of a full-time executive secretary, will carry it out. The state chairman of the Academy for Minnesota is Dr. Roland Nutting who has recently been named to succeed Dr. R. L. J. Kennedy. Full and active support of the pediatricians in Minnesota has been pledged to the study.

Because it is recognized that physicians are exceptionally busy, plans for obtaining the necessary information have been made as simple as possible. The pediatricians, who will be informed of the details of the plan will be called on to contact individual physicians and groups of physicians throughout the state and explain the purposes and details of the plan.

Questionnaires will be used and they will be of several types: those intended for pediatricians, for physicians in private practice, and for hospitals. Local medical societies will be kept informed and local health officers will be asked to take part in the study.

All publicity in connection with the study will be released from the office of the Minnesota State Medical Association. Funds to cover the cost of the study may be obtained from several sources. A request has been sent to the Minnesota State Board of Health asking that funds allocated under Section B, Title 5, of the Social Security Act be made available and it has been requested that the Director of Child Hygiene be instructed to participate in the Study.

Notice has been received from the national office of the survey that the National Foundation for Infantile Paralysis has instructed its regional directors and field representatives to co-operate in this study and to make available funds with which to help defray its cost. The Kellogg Foundation at an earlier date also has made help available.

The desirability of this child health study is quite apparent since the data which will be made available can be used not only for planning by the physicians but also to refute erroneous statements which may be made in support of ill-advised legislation.

It is expected that the actual work of this study will begin in the very near future. This study is of vital concern to the physicians of the state and deserves their full co-operation.

Roger L. J. Kennedy
Chairman, Child Health Committee
Minnesota State Medical Association

THE STATE MEETING—MAY 20-22, 1946

LAST year war restrictions prevented the holding of our annual State Medical Association meeting, except for the House of Delegates. This year the ninety-third annual meeting promises to be unhampered in every way. Those who have been away in the service will have the opportunity of meeting again former friends whom they have not seen for several years or more. Let us make the meeting a real reunion.

The program is being mailed to members well in advance of the meeting. Every effort has been made by the Program Committee to select subjects of new and general interest for the general sessions. On Monday morning, the Minnesota Academy of Ophthalmology and Otolaryngology will hold a separate session; on Tuesday morning the Minnesota and Dakota Orthopedic Club; and on Wednesday morning the Minnesota Chapter of the American College of Chest Surgeons. A scattering of out-of-state talent will add to the program to be presented by local talent in all the sessions.

Demonstrations on Ringworm of the Scalp by the Committee on Child Health and the State Department of Health; on Blood Substitution by the Committee on First Aid and the Red Cross; and Manikin Demonstrations by Dr. M. E. Davis of Chicago will be held each day, and some twenty round-table discussions which have proven so popular of late will add materially to the value of the meeting.

The Saint Paul Surgical Society is writing all interested to attend a dinner meeting Monday evening at which Dr. George M. Curtis of Columbus, Ohio, will be the guest speaker. The annual banquet Tuesday evening will be especially popular as it will be addressed by Dr. James L. Morrill, president of the University of Minnesota, and Dr. Edwin J. Simons of Swanville, president of our State Medical Association.

Make your hotel reservation early or write one of your Twin City friends you are open for an invitation.

COUNTY AND DISTRICT OFFICERS DISCUSS CURRENT MEDICAL PROBLEMS IN STATE

Veteran medical care, prepaid medical service, and the blood plasma and cancer programs for the state were discussed at the annual meeting of the officers of the thirty-four county and district medical societies held Saturday, March 2, in Minneapolis.

Attendance at the conference was over 100, which represents a doubling of the total attendance at last year's session.

What the Veterans Administration expects of Minnesota physicians in carrying out its program of providing the best possible care for the returned GI was explained to the group by Mr. Carl D. Hibbard, manager of Minnesota Veterans Administration, and Dr. Einar Andreassen, recently appointed regional medical director in this area.

"We are in complete agreement with General Bradley in his policy of having local doctors treat veterans wherever possible," Mr. Hibbard said. He reported that within the last three months the number of veterans requiring the assistance of the administration has tripled; and, therefore, it is more important than ever that private physicians assume some of the care of these men.

Family Physician Well Qualified

The veteran's family physician is better qualified than a stranger to care for the veteran since in many cases he has known the patient since birth and may have treated him for childhood diseases or injuries. The family doctor knows the patient's economic status, the nature of his work and even what arrangement for treatment would be most convenient for the patient.

The Veterans Administration is calling upon doctors to make physical examinations for establishing ratings or pensions, Mr. Hibbard said. The doctor's statement will be used by the VA rating board which is composed of a medical specialist, an occupational specialist and a legal specialist. The complete and detailed medical information which the doctor's report will contain is to be used to insure fair and proper rating of cases for pension purposes. The medical member of the board will interpret the medical statements to the other two members; the occupational specialist will determine from the report and the interpretation whether a disability exists and the extent; the legal member will have the say as to whether the law allows pension or compensation for the individual case. The fairness and impartiality of the final judgment in each case, said Mr. Hibbard, will depend upon the completeness of the individual physician's report.

Information should include complete medical history of each disability, disease or injury for which the veteran makes a claim, supported by medical findings, diagnoses and conclusions.

Assure Vets in Rural Areas Proper Care

Dr. Andreassen stressed the importance of another problem of the Veterans Administration, that of the veteran living in a rural area where there may be a skilled physician available, but where there is a lack of equipment and technical aid such as laboratories, x-ray or hospitals. The administration hopes to see a system in effect where the local physicians will make examinations and where possible give necessary treatment, but, hospital and technical facilities lacking, the physician will refer the veteran to the nearest community where he can get proper care.

The Minneapolis Veterans hospital, he said, operating under the new department of medicine and surgery and staffed by men from the University of Minnesota, will be able to handle such cases. An arrangement has been made with the Mayo Clinic to handle certain cases.

It was brought out in the discussions that ordinarily outpatient treatment for service-connected disabilities must be authorized in advance of treatment by the Veterans Administration. However, if a veteran is in need of prompt, emergent treatment and eligibility can be determined from the veteran's papers, the physician may give the necessary treatment, provided he requests authority to do so by mail not later than five days after giving the treatments.

Need for Filing Claim Cited

Dr. Andreassen warned that doctors will undoubtedly be visited by veterans who have not established nor filed claims of service connection for their disabilities. When a veteran does not have a letter from the Veterans Administration stating that service connection for his disability is being allowed, the procedure is to question the veteran to determine whether he has the necessary prima facie evidence. A veteran's statement that he needs treatment for a disability which he believes to be service connected will be accepted by the Veterans Administration as an informal claim which is pending adjudication. The medical statement and the veteran's statement should be sent immediately to the Manager, Veterans Administration, Regional Office.

Dr. Richard B. Hullsiek, chairman of the Medical Advisory Committee on Veterans Affairs, outlined the problem facing civilian doctors when situations arise where veterans after having been out of service several weeks or months become ill and go to their local doctor and either on original examination or after repeated examinations it is determined that they need hospitalization or further medical care. The first thing for a doctor to remember in each case, he said, is that the veteran must put in a claim in order that authority can be granted by the Veterans Administration for medical care that will later be authorized and paid for by the Administration.

The committee is now at work on a plan for Minnesota wherein a satisfactory fee schedule and contract satisfactory to the Veterans Administration and the physicians of the state will be developed which will enlist the service of all physicians to render veterans outpatient care.

University's Contribution Described

Dr. John R. Paine of the University of Minnesota hospitals staff discussed the assumption by the University Medical school of the medical care of patients at the Minneapolis Veterans hospital, a program which has been in effect since November of last year. The two main purposes of the program, that of giving veterans the best medical and surgical advice and treatment available, and of furnishing postgraduate training for a large number of carefully chosen doctors and making specialists of them, were described. The examining boards, Dr. Paine said, have all indicated their willingness to accept training at this hospital as suitable for candidates for certification when the Medical school has acquired the proper staff and has instituted a suitable program.

Measures taken to insure the best of medical care for hospitalized veterans, he said, are already bearing fruit. The most important accomplishment has been the augmentation of the clinical staff of the Veterans hospital. Where previously one doctor had to care for as many as eighty to ninety patients, he now is responsible for no more than twenty to twenty-five. The University program has instituted a department and staff of anesthesia. Up to the present time there has never been trained anesthetists in any of the Veterans hospitals, but now at the Minneapolis hospital veterans undergoing surgery receive the best of modern anesthetic techniques.

Much has been done to alleviate crowding in the hospital by early ambulation following operation and the increasing of the operating room suite from two to six rooms, which is eliminating much pre-operative hospitalization.

"Best Care for the Most at the Least Cost"

Dr. B. J. Branton of Willmar in describing the proposed prepaid medical plan for Minnesota said that what we here in Minnesota want is "the best care for the most people for the least cost."

Minnesotans, he said, are lovers of freedom and democracy and do not want any compulsory type of sickness insurance thrown at them.

The Minnesota State Medical Association at its last House of Delegates meeting elected two men from each of the nine component districts and six delegates-at-large (a total of twenty-four, as a committee to lay groundwork for the establishment of the Minnesota plan.

This committee has studied the plans of many states, finding the one in Michigan to be the best of the non-profit corporations. However, Dr. Branton declared, Minnesota needs "a plan of its own" not a copy of another; it needs a plan which will suit the farmers as well as the businessmen, the specialists in the cities and the rural practitioners, one which will provide not only obstetrical or surgical care, but one which will provide medical care too.

State Plans Co-ordinated at National Level

Speaking to the officers on the proposed national plan for prepaid medical service, Dr. A. W. Adson of Rochester reviewed the work done by the AMA Council on Medical Service and Public Relations in exploring a number of fields for the purpose of setting up a national program. A series of meetings had been held, he said, to examine various suggestions. Dr. Adson described the setting up of the Associated Medical Care Plans Incorporated, the purpose of which was to seek mutual co-operation between all voluntary prepayment medical plans, to maintain a standard, to develop rights of local committees and to make state plans as uniform as possible.

The Council on Medical Service and Public Relations approved the appointment of a director and the necessary staff to advise him and a proposed yearly expense of $50,000. There will be set up a department of prepayment medical insurance in connection with the council with a full-time or part-time director. He and his staff will establish new plans, strengthen ineffective plans and establish reciprocity of benefits in the various states.

The objective throughout in establishing this over-all national plan, said Dr. Adson, shall be not to work at the problem from above, but to start at the base and gradually work up. The answer to the nation's medical care problems, he said, shall be answered without getting the government to help us do it.

Doctor Wells Reviews Cancer Program

Establishment of cancer detection centers throughout the state was the ultimate goal of the proposals discussed for the group by Dr. Arthur H. Wells, pathologist at St. Luke's hospital in Duluth and chairman of the state cancer committee.

The centers described by Dr. Wells are to be free to all persons coming in for examination and staffed by physicians donating their services. Located in hospitals approved by the American College of Surgeons and set up with the approval and under the direct supervision of the various county medical societies, they will be financed by the American Cancer Society. They are a project of the Minnesota State Medical Association and are designed to detect abnormalities which do not produce symptoms sufficient to send the patient to a doctor.

The centers will not diagnose or treat diseases, but where cancer is suspected or indicated, patients will be advised to see their family physician.

At the outset, it is recommended that trial centers be set up in Minneapolis, St. Paul and Duluth; and as soon as it is practical and feasible, centers shall be extended to other communities at the initiation of the county medical societies.

Blood Plasma on Way to Physicians

Physicians in Minnesota will soon receive supplies of dried blood plasma from hospitals in their home communities, Dr. A. J. Chesley, executive secretary of the Minnesota State Board of Health, told the delegates. Donated by the American Red Cross from Army and Navy surpluses, the blood plasma will be supplied through some 193 general hospitals and to four tuberculosis sanatoria throughout the state. It is intended, Dr. Chesley stated, to be used only in cases of extreme emergency where definite need is indicated.

Dr. Paul F. Dwan reviewed for the assembly the medical and surgical conditions that influence a physician's choice of blood substitute. Acute hemmorhage, severe burns, chronic illness, such as cancer, and nutritional anemia were among the conditions that indicate a need for transfusion. Plasma, he said, should be used judiciously, where medically indicated, and where the benefits to be derived overbalance the risks inherent in the intravenous administration of any infusion fluid.

National Officers Speak at Dinner Meeting

After-dinner speakers were two officers in the American Medical Association, Dr. R. L. Sensenich, South Bend, Ind., chairman of the Board of Trustees, and Mr. Thomas A. Hendricks, of Chicago, acting secretary of the Council on Medical Service and Public Relations.

Speaking on the current problems facing medicine today, Dr. Sensenich declared: "A voluntary health insurance program, not a compulsory political program, is the cornerstone around which the budgeting of health costs must be built if the present American system of medicine is to remain unshackled by government bureaucracy."

He stressed the 10-point health program of the AMA and urged that responsibility for getting a fair standard of health should be placed with the individual as far as possible. Federal aid is desirable when needed and if a community is willing to share in the responsibility and the expense.

"Good deeds aren't talked about, bad deeds are," Mr. Hendricks pointed out in his discussion of public relations. Besides his simple definition that public relations is "conduct that should lead to public acceptance," Mr. Hendricks contended that public relations begin at home—that their goodness or badness is dependent on little things like the conduct of the doctor in the patient's home. Bad conduct on the part of as few as one per cent of the individuals in the medical profession or any profession can spoil the whole group effort.

Mr. Hendricks said that an active functioning county medical society can do much to establish good relations. Said he: "The County Society is the best thing American Medicine has." In conclusion, Mr. Hendricks described the responsibility which the County Medical Society today bears, citing the following paraphrase of a statement which Winston Churchill made in a secret report to the House of Commons in the darkest days of the war:

"Testing, trying, adverse, painful times lie ahead of us. We must all strive to do our duty to the utmost of our strength. As the war against regimentation and political medicine rises remorselessly to its climax the medical profession will have the opportunity once again of proving to the world that the firmness of spirit, sense of proportion, steadfastness of purpose which have gained it renown will once again be victorious over bureaucracy. In the final analysis, whatever is to be done must be done through the local societies—the strength, the fight, the fire, the know-how and the 'can do' are in the states and the local medical societies. With your help the job can be done, the job must be done, the job *will* be done!"

CHILD HEALTH SERVICES SURVEY PLANNED

At its morning session preceding the County Officers meeting, the Council approved a plan for conducting a survey of child health services throughout the state, a plan which is to be carried out in co-operation with the American Academy of Pediatrics of which Dr. Roger L. J. Kennedy of Rochester is state chairman. The plan, introduced by Dr. Kennedy, chairman of the state committee on child health, was formulated by the academy two years ago with the establishment of a committee on the study of child health services.

The Minnesota State Medical Association will sponsor the survey in the state to gather information from physicians, hospitals, health and welfare agencies and all other groups involved in health activities. Pediatricians of Minnesota have indicated their willingness to carry out assignments necessary to successful completion of the survey. It is planned that an executive secretary, preferably a physician, will be appointed to set up a central office from which all work on the survey in this state will be directed.

Dr. John Hubbard, who was on the Children's hospital staff in Boston before he entered the medical department of the army, has been appointed general national director with headquarters at the Children's hospital in Washington, D. C. A staff of experts is now at work under him formulating the questionnaires and manual that will be used. In order that the over-all picture will show uniformity, these will be identical in the various states. A pilot study in the state of North Carolina has been used as a guide for mapping future surveys. More detailed information on the survey is to be released as plans get under way.

Minneapolis Surgical Society

Meeting Held December 6, 1945

The President, Robert F. McGandy, M.D., in the Chair

HERNIA IN SOLDIERS: DESCRIPTION OF A NEW INGUINAL OPERATIVE METHOD

HAMLIN MATTSON, M.D., M.S. (Surg.)
Minneapolis, Minnesota

It is an understatement to say that it is a pleasure to return home following service with the armed forces. During most of my service I worked with the Wakeman Hospital Center and related projects for the care of combat wounded. Established before the Normandy invasion, it grew to a bed capacity of 8,000 and was the largest of its type in the army. Many if not most of the patients came by air from the European and Pacific theaters. Eighty per cent of the beds were surgical. As assistant chief of the surgical service my duties consisted in assuming responsibility for the surgery in five of the eight sections of the surgical service.

Such duties permitted among other things the pursurance of an interest of many years in the problem of hernia. The types of inguinal hernia seen were influenced, of course, by the average age of the patients, the screening of induction examinations and the increased muscular development of the soldier.

Final statistical figures for World War II regarding the incidence of hernia at screening examinations are not available as yet. In 1942, 19,923 medical records were selected as representative samples from various states;[17] 64.6 hernial defects were found for each 1,000 men examined. Of 3,000,000 registrants examined from November, 1940, through September, 1941, 43.8 per cent were rejected at local boards and 9 per cent more at induction centers, making a total of 52.8 per cent. In November, 1943, men with hernia which had not descended into the scrotum were accepted. As of May 1, 1944, 4,049,000 of 13,000,000 registrants had been rejected.[18] Of this number, 229,000 or 5.7 per cent were rejected with hernia as the principal cause. Hernia was given as eighth in frequency as a principal cause of rejection.

Increased development of the internal oblique muscle and greater fascial endowments were noticeable during herniorrhaphies on soldiers as compared with the usual run seen in civilian practice. Any doubting Thomas who thinks the internal oblique sphincter action on the internal ring is more theoretical than real, need but put his finger in the neck of an indirect sac when a bulging muscled soldier is recovered partially from anesthesia to be convinced that the internal oblique really does exert a definite and sometimes very strong sphincter action on the internal ring.

Early in the war major surgery was distributed among various installations in the zone of the interior, but later only general hospitals could perform major operations except in emergencies. Hernia repairs naturally were put to unusual stresses and strains by muscular individuals in the exigencies of war. There seemed to be many recurrences. It was while working with direct inguinal recurrences which previously had fascia transplants that I became interested in seeking a better principle of surgical treatment.

There are variations seemingly without end but methods currently in use for the repair of direct inguinal hernia are essentially modifications of a technique described fifty-five years ago by Eduard Bassini[3], a then obscure surgeon at Padua in the swamps behind Venice. The inguinal strata were sutured to their inguinal ligament. Bassini rescued hernia surgery of his day from despair.

Despite improvements in technique in fifty-five years, recurrence rates for direct and recurrent inguinal hernia remain high in the United States. In a recent collection of end-result studies covering a period of ten years, recurrence rates for direct inguinal hernia varied from 2.7 to 33.3 per cent with an average of 15 to 20 per cent.[20] In 1934, Andrews and Bissel[1] reported a recurrence rate of 27 per cent and advocated abandonment of operation for direct inguinal hernia except for pain. Though final figures are not available, it seemed that recurrence rates in the armed services at least were not below those in civilian life. In 1944, admissions to the navy sick list for hernia numbered 16,386[7]; 1,114 were admitted because of recurrent hernia of which 484 were incurred prior to induction.

If it were possible to cover Hesselbach's triangle from the pubic spine with a layer of thick aponeurosis and anchor it to a solid structure by sewing clean fascia to clean fascia, better results should be possible generally. In the fall of 1943, on soldiers from the California desert training center, I began to turn back a flap of rectus to the superior pubic ligament for a distance of 5 centimeters out on that ligament, anchoring the rectus flap with interrupted silk sutures. The inguinal ligament was ignored. To be certain that an indirect sac was not overlooked, the cremaster envelope was opened in each case. If it is looked for, a projecting tongue of peritoneum can be found nearly always at the internal ring. Whenever necessary the transversalis fascia was sewed with interrupted silk around the actual structures of the cord.[13]

Much surgical and anatomical water has gone over the dam since Bassini's day, and the inguinal structures have been restudied with greater care. Recently the very basis of the Bassini operation has been challenged openly. After a dissection of 300 inguinal regions with the thought of continuity of aponeurosis and fascia in mind, McVay, in 1939[14], described the inguinal ligament as essentially a guy-rope. "The inguinal ligament," he writes, "is not the site of insertion of either the transversus abdominis or internal oblique muscles, nor is it anchored securely enough to its fascial surroundings to serve as a substitute for this insertion." He states that "pure fascia does not have the strength necessary to repair a muscule-aponeurotic defect such as occurs in direct inguinal hernias." He found that "the lowermost fibers of the internal oblique and transversus abdominis muscles do not attach to the inguinal ligament but insert into the fibrous covering of the pubic pecten, the ligamentum pubicum superius (ligament of Cooper)." According to his findings, the conjoined tendon usually is an artifact of dissection. In 7 per cent of dissections, he found the lower transversus abdominis deficient. This year Brandon[5], commenting in the British journal, *Lancet,* on the "house Bassini built" states that if a house persists in falling down in spite of having immensely strong walls, it can only mean that no one has examined the foundations with sufficient care.

Superior Pubic Ligament

Sir Astley Cooper described the superior pubic ligament (BNA) in 1804. He is reported to have advised its use in inguinal hernia operations. Anatomists and surgeons have paid little attention to it through the years. The twenty-fourth edition of Gray's Anatomy[9], published in 1942, gives it just four lines of fine print. It is a strong fibrous band extending lateralward from the base of the lacunar ligament along the pectineal line of the superior pubic ramus, to which it is attached firmly. It is strengthened by the pectineal fascia and by a lateral expansion of the lower attachment of the linea alba called the adminiculum linea alba. Lotheissen[12] reported using it in inguinal and femoral hernia in 1898. He encountered a forty-five-year-old woman who had been operated on twice before by the Bassini method. In May, 1897, he found the inguinal ligament destroyed and resorted to the use of Cooper's ligament. He quoted Narath of Utrecht as having performed the same procedure under similar circumstances. Subsequently, this method has been used in Europe and America. Babcock[2] sutured the uncut rectus sheath to the dense fibrous covering of the pubic pecten in 1927. Dickson[6] suggested ignoring the inguinal ligament entirely in 1936. Recently at Henry Ford Hospital in Detroit, practically all inguinal hernia operations have been done by the superior pubic ligament technique.[11]

In November, 1943, I applied the method used by Harkins. To relieve tension on the suture line I made a linear incision in the rectus sheath as he did. Because of dissatisfaction with the relaxation thus produced and the inadequacy of the transversus abdominis in certain cases, I turned down a flap of rectus and pyramidalis sheath, a method which had been applied to the inguinal ligament.

The Rectus Sheath

Bassini is said to have used the rectus sheath often in closures. In 1892, Wolfler[21] cut the rectus sheath and used it in hernia repair. Slajmer (1898) reported on 150 cases using Wolfler's method.[19] His drawing shows an incomplete rectus flap sewed to the middle third of the inguinal ligament. The flap was not cut down to the pubis. Berger[4] (1902) and Halstead[10] (1903) turned down full flaps of rectus fascia in inguinal hernia repair. In 1941, Estes[8] reported 2.77 per cent recurrences in 72 cases of direct inguinal hernia in which he used the rectus flap inguinal ligament method.

The so-called conjoined tendon often is a very flimsy structure. McVay found it usually was an artifact of dissection. In 1940, Riehoff[16] dissected 200 cadavers and found difficulty in demonstrating a conjoined tendon.

Description of Method

The incision ordinarily used for hernioplasty is placed a centimeter superiorly and a centimeter medially to the site usually used. The aponeurosis of the external oblique is split over the cord and the cord and cremaster envelope separated from its bed and the superior ramus of the pubis palpated.

The cremaster envelope is opened at the internal ring and the actual structures of the cord isolated. A peritoneal pouch has been looked for and found in each case. The pouch is opened, a finger inserted into the peritoneal cavity, the strength and redundancy of the floor of Hesselbach's triangle evaluated and it is decided then and there as to whether or not it needs re-enforcement. The transversalis fascia is sutured around the actual structures of the cord as a collar and the cremaster envelope closed. The direct sac is disposed of.

The superior pubic ligament is exposed by blunt dissection beginning at the spine of the pubis. The left index finger is used against the femoral vessels as a retractor. After about 6 centimeters of the ligament have been exposed, a boomerang-shaped flap is cut from the anterior sheaths of the rectus and pyramidalis muscles. Fine interrupted silk sutures are placed. Then the upper portion of the rectus sheath flap and available fascia is sutured up to the cord.

Indications

The method described above seems indicated in (1) direct inguinal hernias; (2) indirect inguinal hernias where the fascia of Hesselbach's triangle as shown by the palpating finger within the abdominal cavity is weak or redundant; (3) recurrent inguinal hernias and (4) femoral hernias.

Discussion

The above can be only in the nature of a preliminary report. I have operated upon thirty-five patients in military service since July 1, 1944, employing the above principles. It is my opinion that the operation is sound in principle and gives promise to lower recurrence rates in its field. It is well known that the most vulnerable area for recurrence in direct hernia is the lower angle where in the Bassini operation, two more or less fixed structures are sewed together. This cannot be done without tension as emphasized by Stein and Casten.[20] As pointed out by McVay[14], the transversalis in this angle sometimes is developed poorly. Rectus aponeurosis meets this deficiency and in this respect seems to be an improvement over procedures involving the superior pubic ligament described heretofore.

Postoperatively the examiner gets little or no impulse against the examining finger on cough when the finger is introduced into the internal ring.

The advantage of the procedure in recurrent hernia is that previously worked over scar-laden tissues are avoided and the operation is carried out in a virgin field largely. Recurrence rates should therefore approximate those of the primary operation.

The suture of the transversalis fascia as a collar around the actual structures of the cord gives the advantage which Halstead obtained by removing the cremaster entirely and approaches the insurance against recurrence of removal of the cord and testicle.

The sphincter action of the internal oblique at the internal ring is not disturbed.

Operating on both sides at the same sitting by one of the Bassini or previously performed Cooper's ligament methods, increases definitely the tension at the main suture line. This can be demonstrated readily in the cadaver. Such an objection does not apply to the method just described by me.

Superior pubic ligament procedures safeguard against overlooking an occult femoral hernia, and if a femoral hernia is encountered, the operation above described takes care of it more adequately than any of which I know. It may be said about the general uses of this operation that, in fact, you are damming the waters upstream where the gorge is narrowest with strong aponeurosis rather than below in the broader plain, where the structures part at the seams.

Summary

A method of hernioplasty is described wherein a flap of anterior rectus and pyramidalis sheath is turned down and sutured to the superior pubic ligament. Such a procedure is believed indicated in (1) direct inguinal hernias; (2) indirect inguinal hernias with weak and redundant fascia in Hesselbach's triangle; (3) recurrent direct inguinal hernias operated on previously by other methods; and (4) femoral hernias.

Discussion

Dr. Ivar Sivertsen: It has been my pleasure to have the privilege of seeing Doctor Mattson do this work. In fact, I have had him take care of a couple of cases of inguinal hernia as well as one case of femoral hernia by this method.

I think the principle Doctor Mattson has in mind is excellent and his results should be perfect. There is one thing that I feel is necessary in this procedure and that is that the surgeon must know his anatomy. He must recognize the large vessels present and when he applies his sutures he must be sure that he does not injure the femoral vessel, and in this way produce a thrombosis.

The drawing of the flap down to the pectineal line where the ligament is attached, and this part of the rectus muscle brought into position certainly gives excellent support to the deeper structures.

The three cases which were done by Doctor Mattson for me have had excellent results. No impulse is noted when the finger is placed in the external ring.

I congratulate Doctor Mattson on this fine piece of work, and thank him for bringing this matter to the attention of the society.

Dr. Kenneth Bulkley: Doctor Mattson has presented us with a most excellent paper on the subject of hernias, with particular reference to the adequate closure of direct inguinal hernias. Satisfactory permanent closure of these direct hernias is not, as you all know, always easy. We have, all of us, too often in the past seen such hernias, which we closed merely by suturing the edge of the rectus sheath to Poupart's ligament, recur. With this procedure the tension is too great. Doctor Mattson has presented a method of closure by means of turning back a trap door from the anterior rectus sheath, this procedure relieving tension.

There is a further suggestion or two which I would like to make. In the third slide, which he showed tonight, you will note that he has made his trap door in a semi-circular manner. If this flap is made in a rectangular shape, carrying the far side of the rectus flap to the midline, as advocated many years ago by the late Dr. Joseph A. Blake, it will be found that the tension is still less, and that a broader edge is thus obtained for suture to Poupart's ligament. Furthermore, when this suture is completed, and the so-called conjoined tendon and the aponeurosis of the external oblique also sutured beneath the cord, leaving the cord subcutaneous, a firmer and more solid closure will be obtained. I feel this closure is more solid than that obtained by the Gallie procedure. Patients occasionally complain of discomfort in the cord following such subcutaneous transplantation, but such is always only temporary. Incidentally, I might add that I prefer sharp rather than blunt gauze dissection in these procedures.

Dr. Clarence Dennis: I would like to ask one question. There has been some mention by various members of the Society recently of dissecting all the structures of the cord except the vas and the vessels. I am curious to know if most of you gentlemen employ this technique or not. It does seem that it should lower the recurrence rate, although there is probably an increased reason for atrophy of the testicle. In regard to this very excellent paper by Doctor Mattson, in the past two years, we have been teaching our students at the University the McVay-Harkins procedure. It seems to us that this is the most adequate of all the hernioplasty procedures which have been devised. This procedure suggested by Doctor Mattson, however, seems to be workable in conjunction with the McVay-Harkins.

After listening to this paper, I for one plan to try Doctor Mattson's procedure simply to see how it works. This has been a most illuminating paper.

Dr. Mattson: The question was asked as to whether the transversalis could be sutured as a cone cuff pointing intra-abdominally about the actual structures of the cord. I should think that would be difficult, but perhaps possible. I have not tried it. The transversalis fascia is a thin layer and seems to just come together around the actual structures of the cord, within the cremaster envelope.

In Babcock's operation the edge of the rectus sheath is sutured to the lower portion of Cooper's ligament. In the operation which I have described, the turned-back flap of rectus sheath is sutured out almost 5 centimeters from the spine of the pubis.

I appreciate Doctor Bulkley's remarks on sharp dissection. I was brought up on sharp dissection but believe there are a number of instances in surgery when blunt dissection with gauze is called for. One of these, in my opinion, is the exposure of the superior pubic ligament where the areolar tissue can be wiped away and injury to vessels guarded against. Most of the exposure must be by blunt dissection. Gauze dissection is the method used quite generally in exposing Cooper's ligament in the country at large, according to the literature.

The anterior rectus sheath is exposed and taken medially as far as the attachment of the external oblique will permit. Hence, in the procedure I have described, as wide a flap as possible is taken consistent with leaving the external oblique intact.

May I say a word about early rising. The rectus sheath, superior pubic ligament procedure using interrupted silk seems to lend itself well to early rising. Before early rising was interdicted by the surgeon general, I got some of those patients up on the third and fourth day.

As Doctor Sivertsen has indicated, injury to the femoral and deep eipgastric vessels must be guarded against. The index finger serves as a retractor and guards the femoral vessels, and I have found it safest to isolate the epigastric vessls much as a nerve is isolated to keep it out of harms way.

ACUTE ACROMIO-CLAVICULAR JOINT DISLOCATION

Internal Fixation of the Clavicle and Coracoid Process of the Scapula with a Vitallium Screw

ROLLA STEWART, M.D.
Minneapolis, Minnesota

This condition, as the name implies, is a dislocation of the outer end of the clavicle from the acromion of the scapula.

Function of the Acromio-Clavicular Joint

When the shoulder is projected backward, the acromion slides very little because the capsule and the acromio-clavicular ligament are immediately placed under tension, and the joint has a tendency to open. The clavicle follows to a certain extent this backward movement, but is stopped by the tension of the trapezoid ligament. Exactly the opposite occurs when the shoulder is forced forward. As the acromion slides, the acromio-clavicular joint has a tendency to close and the conoid ligament under tension stops the forward movement of the clavicle. When the shoulder is forced upward with the arm in full extension, the conoid ligament is the first to resist.

Anatomy

The integrity of the acromio-clavicular joint is maintained principally by the two powerful coraco-clavicular ligaments, the conoid and trapezoid, and to a lesser extent by the acromio-clavicular ligament. The acromio-clavicular joint is the only union between the scapula and the clavicle and is a very important connecting link between the trunk and the upper extremity. This joint has an intra-articular meniscus and a capsule that is reinforced on its superior aspect by the acromio-clavicular ligament. The fact that its main elements of fixation are quite far away from their articular surfaces, gives it a peculiar feature.

Classification

Acromio-clavicular joint dislocations may be classified into two types: (1) incomplete; (2) complete. In a review of the literature some authors, in using such terms as luxation or subluxation of the acromio-clavicular joint, have not made it clear as to whether they were treating a complete or incomplete separation at the acromio-clavicular joint. This should be made clear because the satisfactory conservative treatment for an incomplete dislocation will not cure a complete dislocation.

Clinical Anatomy

As a means for heavy weight traction and pushing, the shoulder is admirably suited to its task, since it is well supported by strong muscles and allows movement in practically any direction. However, the stress produced by a sudden blow directed against the tip of the shoulder, or a fall on its outer end, will unduly tax the acromio-clavicular joint. Not infrequently there follows a varying degree of separation at the joint with stretching or tearing of the capsular and associated ligaments. Blows to the outer end of the acromion process are transmitted to the well-cushioned scapula directing it downward and inward. Because of the position of the first rib at the clavicular attachment to the sternum, the outer end of the clavicle is able to follow this downward and inward movement only a fixed distance. When the limit of movement is reached, either the clavicle fractures or one of its two ligaments must yield, providing the force exceeds the strength of the weakest link in the structure.

If only the acromio-clavicular ligament is torn, there will be little or no separation at the joint. Cases of this type are always cured by taping or strapping for a period of eight to ten days.

If the force producing the injury is great enough, the coraco-clavicular ligaments will be torn as well, resulting in wide or complete acromio-clavicular separation. In such cases, no amount of strapping or taping will cure the dislocation.

Complete Separation

Symptoms.—The degree of disability in complete acromio-clavicular joint dislocation should not be underestimated. The patient complains of instability of the shoulder joint and there is constant nagging pain. There is difficulty in abducting the arm beyond 90 degrees. The reason for the disability is explained by the fact that abduction to 90 degrees occurs in the glenoid fossa of the scapula. Abduction beyond 90 degrees brings into play the acromio-clavicular joint. With dislocation of this joint, the pain and difficulty in abducting the arm beyond 90 degrees can be readily understood.

Diagnosis.—Although a suggestive history and typical physical findings will establish the diagnosis in most cases, it is always advisable to examine the area by roentgen ray. A large film should be used so as to include both clavicles on the same film. In this manner, there is set up a normal study of the clavicle of the individual to be examined. The patient should be in a standing position with both arms hanging free and unsupported. It is well to keep in mind that most acromio-clavicular joint separations fall back into normal position when the patient is placed in the horizontal position and may give an erroneous x-ray study. This can be avoided if a pull is exerted on the arms at the time the x-ray is taken on patients who are bedridden.

Principles of Treatment.—Since good results are obtained by conservative methods in partial or incomplete separations, further discussion will be directed toward the acute complete acromio-clavicular joint dislocation. Regardless of the degree of dislocation, a reduction can usually be effected in fresh cases of elevating the shoulder upward and forcing the outer end of the clavicle downward, thus opposing the joint surfaces. Uninterrupted maintenance in this position for a period of several weeks will allow the ligaments to heal. Since the involved ligaments, like fibrous tissue elsewhere in the body, will heal if held in apposition, it is evident that the value of any treatment, whether conservative or surgical, lies in maintaining rather than obtaining reduction.

Various dressings have been devised to hold the shoulder and clavicle in the corrected position. The majority of these are based on the principle of support of the arm of the injured shoulder by means of adhesive, plaster, cloth, or a metal brace, so placed that the pull of gravity on the arm is counteracted by the compressing support of the dressing. Although theoretically sound and effective when secure, dressings of this type soon loosen and slip with respirations and body movements, thus allowing a return of the dislocation. It is this ineffectiveness which has resulted in the widespread abandonment of conservative treatment.

The first attempt at a surgical repair of acromio-clavicular dislocation was made in 1861 by Cooper. He wired the outer end of the clavicle to the acromion. Paci, in 1899, resected the ends of the dislocated bones and arthrodesed them. Budinger, in 1900, fastened the bones together with screws. Tuffier, in 1914, used silk; and Delbet, in 1916, fastened the bones with nails. Later he employed a bone graft. Cadenat, in 1917, attempted an anatomical repair of all the torn ligaments with silk; while Bunnell, in 1928, comprehensively described the operation used today employing fascia lata. Although Bunnell is considered the pioneer in the fascial repair of acromio-clavicular dislocation, credit must be given to Henry who performed this operation as early as 1924. Watkins, in 1925, reported his work. In place of fascia, he repaired the coraco-clavicular ligament by means of a silk ligature passed around the clavicle and the coracoid process of the scapula. However, his operation was not only an extensive one, but in the hands of many surgeons failed to give satisfactory results. Two years previous, Hart reported his method of applying a plaster-of-Paris shoulder spica cast with the arm abducted at a 45-degree angle. After four weeks he removed the top shell of the cast for the purpose of allowing motion. He figured six to eight weeks as the healing period.

Within the last few years there has been a growing tendency to abandon the radical surgical repair of the coraco-clavicular ligament in favor of simpler procedures. In 1940, Murray reported his method of passing one or two Kirschner wires through the acromion process across the acromio-clavicular joint into the outer third of the clavicle. Although he reports five cases, all successful, some of the photographs in his article showing the wire in place, also show that the dislocation is not completely reduced. In most of his cases, he eventually removed the wires. Since they pass through some of the deltoid muscle fibers they cause pain on abduction at the shoulder joint. Phemister, two years later, reported his method of passing two fairly heavy threaded steel wires through the acromion process into the distal third of the clavicle. He kept the arm in a Velpeau bandage for one month and after two months removed the wires and allowed free use of the arm. Although it is a simple procedure to pass one or two wires across the acromion process of the scapula into the distal third of the clavicle, this is the only surgical procedure that has developed a serious complication.

"SMOOTHAGE" FOR THE CONVALESCENT

By promoting normal peristalsis without irritating the delicate mucosa, Metamucil is particularly desirable for treating the constipation of hospital patients.

Metamucil provides "smoothage" . . . a modern concept for the treatment of constipation. It does not interfere with digestion or absorb oil-soluble vitamins. It is rapidly miscible, pleasantly palatable.

Metamucil is the highly-purified, nonirritating extract of the seed of the psyllium, Plantago ovata (50%), combined with dextrose (50%). In 1-lb., 8-oz. and 4-oz. containers.

Metamucil is the registered trade-mark of G. D. Searle & Co.

SEARLE RESEARCH IN THE SERVICE OF MEDICINE

(Continued from Page 358)

In 1942 Mazet reported two cases where the wires had migrated into the pleural cavity.

In 1941 Bosworth reported four cases wherein he ran a vitallium screw through the outer end of the clavicle into the coracoid process of the scapula. I used this technique in nine patients operated upon in the Minneapolis General Hospital in 1942 to 1944.

Technique of the Operation

The patient is placed on the operating table with the back elevated about 35 degrees. After the skin is properly prepared and sterile drapes applied, the remaining portion of the operation is performed under local anesthesia. A three-inch skin incision is made over the tip of the shoulder. The incision begins two inches from the distal end and near the posterior border of the clavicle, then is curved to run anteriorly one inch further over the acromio-clavicular joint. The distal end of the clavicle and the acromio-clavicular joint are exposed by splitting the deltoid muscle fibers that run parallel over the lateral tip of the clavicle. At this stage of the operation, local anesthetic is infiltrated into the region of the acromio-clavicular joint so as to abolish pain when reduction of the dislocation is attempted. Reduction of the dislocation is a simple procedure. The distal end of the clavicle is forced downward while at the same time the shoulder is elevated upward. If the acromio-clavicular joint is sufficiently exposed surgically, one can be certain of a complete reduction. Occasionally, the articular surface of the acromion lies anteriorly or posteriorly to the distal end of the clavicle after the downward separation has been reduced. This can be corrected under vision merely by forcing the acromion backward if there is an anterior dislocation or forward if there is a posterior dislocation. With the reduction of the dislocation maintained, a hole is drilled through the clavicle. The drill hole should be slightly larger than the diameter of the screw and should be placed 1 to 1.5 inches from the distal end of the clavicle. The proper site can be determined as follows: A long needle attached to a syringe of 1 per cent novocain solution is inserted near the anterior surface of the clavicle in line with the tip of the coracoid process. The needle is directed downward and obliquely posteriorly. The medial border of the coracoid can be palpated with the needle and the drill hole placed 0.25 of an inch lateral to the needle. If novocain solution is injected with the progress of the needle, the procedure is painless. After the hole is drilled through the clavicle, 1 per cent novocain solution is injected through the drill hole around the coracoid process. Entering the drill hole in the clavicle, a small drill hole is then made into the outer cortex of the coracoid process. A small washer is placed over the drill hole in the clavicle and a partially threaded vitallium screw 1.5 to 1.75 inch in length is inserted through the clavicle into the base of the coracoid process. The screw should be firmly tightened since there is no danger of overcorrection. The incision is closed with non-absorbable skin sutures or metal clips, and protected with a small sterile dressing. The patient is advised to refrain from abducting the arm beyond 90 degrees and not to use the arm for lifting or pulling while the screw is in place. The screw should be removed in six to eight weeks.

I have been questioned regarding the danger of the screw injuring the axillary artery or vein when inserted into this particular site in the body. Bosworth answered this question. He made a frontal section through a frozen cadaver and found that the axillary artery and vein lie well anterior and out of danger from injury by the screw. If too long a screw is used, the point of the screw merely imbeds itself in the subscapularis muscle and apparently causes no difficulty.

Conclusions

1. Nine patients with acute complete acromio-clavicular joint dislocation have been operated upon showing that it is possible to insert a screw through the distal end of the clavicle into the coracoid process of the scapula which will maintain continuous reduction of the dislocation.

2. It is essential that the patient refrain from heavy weight traction on the arm and refrain from abducting the shoulder beyond a 90-degree angle; otherwise the screw will tear out or break.

3. After a period of six to eight weeks the screw should be removed and the patient then is allowed free use of the arm and shoulder.

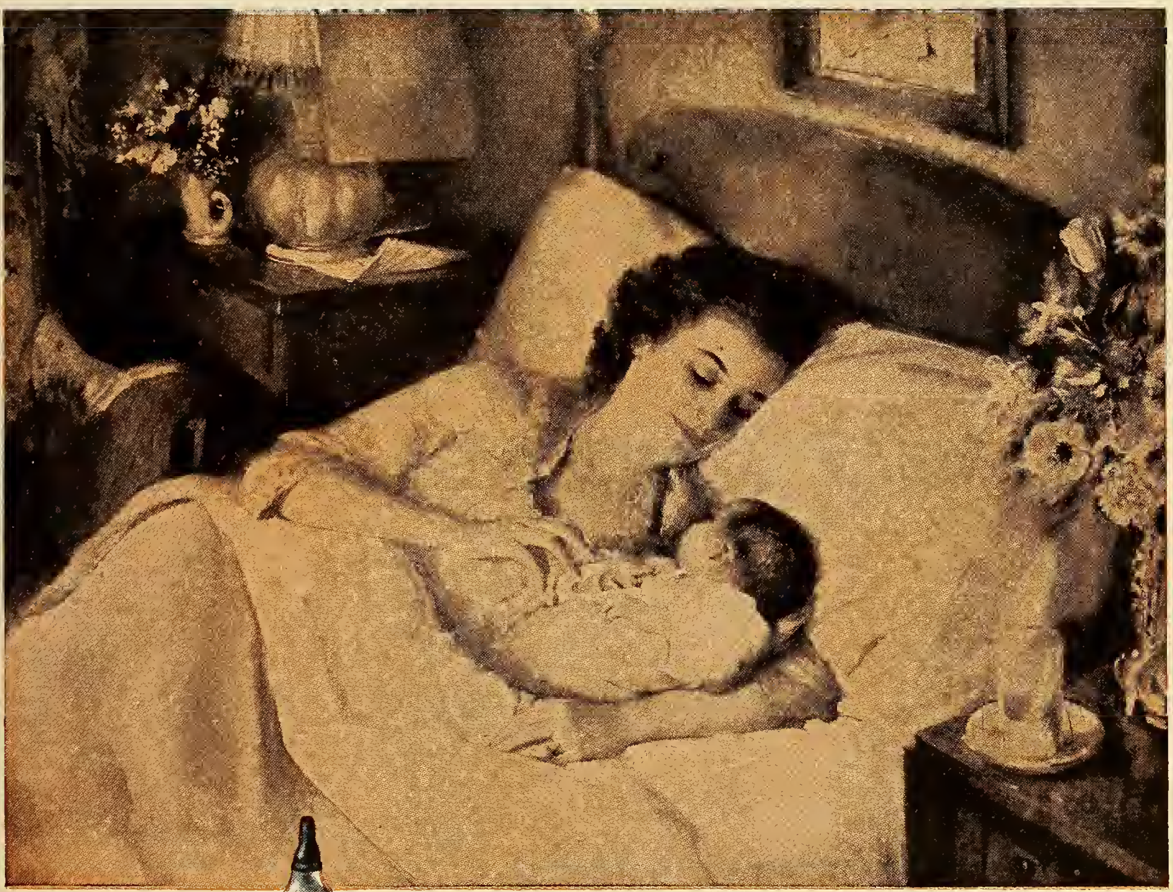
The First Year

THE SUCCESSFUL NUTRITIONAL history of S-M-A babies is due to the remarkable similarity of S-M-A to mother's milk. It is essentially the same as human milk in percentage of protein, fat, carbohydrate and ash, in chemical constants of the fat and in physical properties.

S-M-A* IS RECOMMENDED for normal, full term infants in the early weeks of life when a supplementary food is required for the breast-fed infant. It may be given to infants of any age whenever the mother's milk is unavailable, of poor quality or insufficient quantity.



S-M-A is derived from the milk of tuberculin-tested cows. Part of the butter fat of this milk is replaced with animal and vegetable fats, including biologically assayed cod liver oil. Milk sugar, vitamin A and D concentrate, carotene, thiamine hydrochloride, potassium chloride and iron are added. *REG. U. S. PAT. OFF.

FOR SALE BY SURGICAL DEALERS AND DRUGGISTS

For preoperative and postoperative use

Demerol hydrochloride, administered from thirty to ninety minutes preoperatively, relieves much of the surgical patient's apprehension and reduces the amount of anesthetic agent required to obtain a given depth of narcosis. The average preoperative dose for adults is 100 mg. injected intramuscularly, which may be combined with scopolamine or a barbiturate to assure amnesia.

Compared with morphine, Demerol causes considerably less nausea and vomiting, and the danger of respiratory depression is greatly reduced. Unlike morphine, Demerol does not interfere with the cough reflex or the reflexes and size of the pupil. It does not cause constipation, and urinary retention is less than with morphine.

Postoperatively, Demerol is a reliable analgesic in the majority of cases, regardless of the type of surgery or the severity of pain. Patients in the older age group, in particular, respond most favorably to this drug. The average postoperative dose for adults varies from 50 to 100 mg., administered by intramuscular injection or by mouth.

U. S. PUBLIC HEALTH SERVICE

Examinations for appointments of medical officers in the Regular Corps of the United States Public Health Service will be held at various convenient localities throughout the country. Examinations are for appointments to fill vacancies of Assistant Surgeon (First Lieutenant) and Senior Assistant Surgeon (Captain).

Regular Corps appointments are permanent. They provide qualified doctors with opportunities for a career in one or more of a number of fields including research, general hospitals, special hospitals, foreign duty, and public health programs.

Entrance pay for Assistant Surgeon with dependents is $3,411 a year, and for Senior Assistant Suregon with dependents is $3,991 a year. Promotions are at regular intervals up to and including the grade of Medical Director which corresponds to full Colonel at $7,951 a year. Retirement pay at sixty-four is $4,500 a year. Full medical care including disability retirement at three-fourths pay is provided. All expenses of official travel are paid by the Government. Thirty days' annual leave with pay is provided.

Applicants for the grade of Assistant Surgeon must be citizens of the United States, must present diploma of graduation from recognized medical school, must have had or be in the process of completing the seventh year of college or professional training or experience since high school graduation (two years premedical, four years of medicine, one year internship), and must have a physical examination at the place of oral examination by medical officers of the Service. Applicants for the grade of Senior Assistant Surgeon must meet the above requirements and must have had four additional years of postgraduate training or experience.

Examinations will be oral and written. The written examination will be held on May 14, 15 and 16 at places convenient to the candidate and the Service. National Board grades may be used for the Assistant Surgeon examination. An oral examination will be held at 9 a.m. at the Office of Indian Affairs, 218 Federal Office Bldg., Minneapolis, Minn., April 29, 1946.

Application forms may be obtained by writing to the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

ILLINOIS OTOLARYNGOLOGY REFRESHER COURSE

A one-week didactic and clinical refresher course in Otolaryngology has been arranged for specialists in the field, from May 13 to 18, 1946, inclusive. Applications for registration should include school of graduation, training and experience. Check for tuition ($50.00) should accompany the application.

In addition, a special course in Broncho-Esophagology will be given from June 3 to 15, 1946, inclusive. It will consist of lectures, animal and cadaver demonstrations, diagnostic and surgical clinics.

The course will be under the direction of Dr. Paul H. Holinger and Dr. Albert H. Andrews, Jr.

Tuition for this course is $100.00. Check should accompany application. Class limited to twelve physicians.

Further information may be obtained by writing to the Department of Otolaryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago, Illinois.

ATTENTION WOMEN DOCTORS!

On Monday, May 20, a 12:15 luncheon for women doctors attending the annual meeting of the Minnesota State Medical Association will be served in a private room at the YWCA situated across the street from the Auditorium. The price is $1.00.

Dinner will be served Monday evening at the Women's City Club, 305 St. Peter. Tickets are $1.50.

Please make reservations early through Dr. Nellie N. Barsness, 540 Lowry Medical Arts Building, Saint Paul 2, Minnesota.

E. STARR JUDD LECTURE

The thirteenth E. Starr Judd lecture will be given by Dr. Samuel C. Harvey, Wm. H. Carmalt Professor of Surgery at Yale University, Monday evening, April 15, 1946 at 8:15 in the Medical Science Amphitheatre. Subject is "The Healing of the Wound."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in Surgery a few years before his death.

WASECA COUNTY SOCIETY

Dr. and Mrs. Homer M. McIntire entertained members of the Waseca County Medical Society and their wives at dinner at their home in Waseca on the occasion of the society's annual meeting. After dinner both the society and the auxiliary held their business meetings and elected the following officers: Dr. George H. Olds, of New Richland, was made president of the Medical Society and Dr. Siegfried Oeljen, secretary-treasurer. The auxiliary named Mrs. McIntire president, and Mrs. Olds as secretary-treasurer. Resolutions were passed asking adjustment of nurses' salaries to a fair comparison with those in similar institutions in the locality, and urging the hospital board to increase hospital capacity.

WASHINGTON COUNTY

The members of the Washington County Medical Society were addressed at their regular monthly meeting March 12, 1946, by Dr. Karl H. Pfuetze, Medical Director and Superintendent of the Mineral Springs Sanatorium. His subject was "Tuberculosis," and chest x-rays were presented. Dr. Pfuetze also spoke on the uses and effects of the newer drugs on this disease as well as the effect of the newest drugs, not yet available for the general practitioner.

SPRING CLINIC—CRIPPLED CHILDREN SERVICES

The Division of Social Welfare, Medical Services Unit, announces the Spring Clinic Schedule for Crippled Children Services as follows:

Worthington	May 18	Nobles Jackson Murray Rock Pipestone Cottonwood	Grade School
Grand Rapids	May 25	Itasca Koochiching Cass	Senior High School
Morris	June 1	Stevens Pope Douglas Grant Traverse Bigstone Swift	High School
Detroit Lakes	June 8	Becker Clay Mahnomen	High School

Registration Hours: 8:00 a.m. to 2:00 p.m.

NURSES' ASSOCIATION ANNOUNCES COUNSELING AND PLACEMENT SERVICE

The Minnesota Nurses' Association announces the establishment of a Professional Counseling and Placement Service with offices at 2642 University Avenue, Saint Paul 4, Minnesota. The purpose of this service, for which there is no fee to either employer or employe, is three-fold: to help place nurses and auxiliary workers in the geographic area and in the nursing service where there is the greatest need; to help nurses, auxiliary workers, and prospective nurses make the best adjustment to the profession by helping them solve their educational, vocational and personal problems; to provide a place for employers of nurses to report their nursing needs and to get help in filling the vacancies in their nursing staffs.

DINGELL-DANGELL-DINGELL

Well, here it is, the bill of bills,
The Wagner-Murray-Dingell
'Tis said 'twill help cure all your ills;
(Such talk is just a jingle.)

These are the facts that you should know
No matter what your station:
The Surgeon General plans to rule
The health of all the nation.

Sixteen he picks to counsel him
From lists of every kind.
They'll counsel him, but in the end
He'll make up his own mind.

The Council makes reports, that's all.
For this they get good pay.
An awful waste of tax funds, this,
At twenty-five a day.

Your tax for this is four per cent;
Employers pay the same.
And if you're working for yourself,
Your tax is more!—Some game!

Three billion bucks a year that makes
That for the Surgeon General's slated.
If doctors don't do what he says
They're excommunicated!

You can't select a doctor or
A dentist or a nurse,
Unless the Surgeon General
Has picked them for you first.

Why change to socialism now?
As this bill would, no doubt.
Is this America or not?
It's time that we found out.

—By Sue Dickey Hough
Former member, Minnesota State Legislature

The first wealth is health. Sickness is poor-spirited, and cannot serve anyone; it must husband its resources to live. But health answers its own ends, and has to spare; runs over, and inundates the neighborhoods and crooks of other men's necessities.—Ralph Waldo Emerson.

YOU CAN'T OVERRATE THE VALUE OF CONTROL

Everyone can see the need for control measures against *obvious* dangers. But dramatic and constant campaigning is necessary to win public support in the fight against the unseen menace of cancer. Interest must be awakened and education conducted to enlist the public co-operation requisite to success. This challenging work is the responsibility of the Field Army of the American Cancer Society.

To give appropriate significance to these efforts and to focus nation-wide attention on this vital problem, Congress has designated April, "Cancer Control Month." And again this Spring, as in each drive spearheading the next year's activities, the Field Army's straightforward appeal to all Americans is: "GIVE, to Conquer Cancer."

Once more, over 10,000 Rexall Drug Stores across the country unite in behalf of this cause. Urging Americans to heed the Society's plea, these stores contribute facilities for distribution of literature cautioning "Consult your doctor" at the first moment of cancer's "danger signals."

WOMAN'S AUXILIARY

MRS. EDWARD V. GOLTZ, *President*
Saint Paul, Minnesota
MRS. JOHN K. BUTLER, *Editor*
Carlton, Minnesota

Blue Earth County

Dr. Haddow M. Keith, Section on Pediatrics of the Mayo Clinic, addressed the Blue Earth and Nicollet-Le Sueur County Auxiliaries on February 18 at the Lincoln School auditorium. His subject was "Mental Hygiene," with reference to child health. The meeting was open to the public.

Two members of the auxiliary, Mrs. A. F. Kemp of Mankato, Chairman of the Society for the Control of Cancer, and Mrs. J. C. Vezina of Mapleton attended the three-day Cancer School at the University of Minnesota.

Goodhue County

Mrs. F. R. Hedine and Mrs. R. V. Sherman, both of Red Wing, are on the local committee of the Minnesota Association for Crippled Children and Adults. All of the members of Goodhue County Auxiliary are participating in the annual cancer control drive. The Auxiliary is making plans for an April luncheon to welcome three new members: Mrs. Grant Hartvagel, who has returned to Red Wing with Dr. Hartvagel, recently discharged from the service; Mrs. James Weir of Goodhue, and Mrs. Ralph Larson of Cannon Falls.

Kandiyohi-Swift-Meeker Counties

Mrs. Hans Johnson of Kerkoven was hostess to the Auxiliary of which she is president at Willmar, Minnesota, on January 13.

St. Louis County

Mrs. L. E. Schneider of Duluth, a member of the Auxiliary, gave an enlightening and stimualting review of *Where People Take Their Troubles* by Lee Steiner at the monthly luncheon meeting of the Auxiliary in the Holland Hotel, Tally Ho room, on February 12.

Mrs. G. Arvid Hedberg, president of the Auxiliary, gave a résumé of Dr. Weaver's talk at the State Board meeting.

Mrs. M. A. Nickolson, chairman of the Philanthropic Committee, reported the gift of a card table and four chairs to the Nopeming Sanatorium, one room of which has been a project of the Auxiliary.

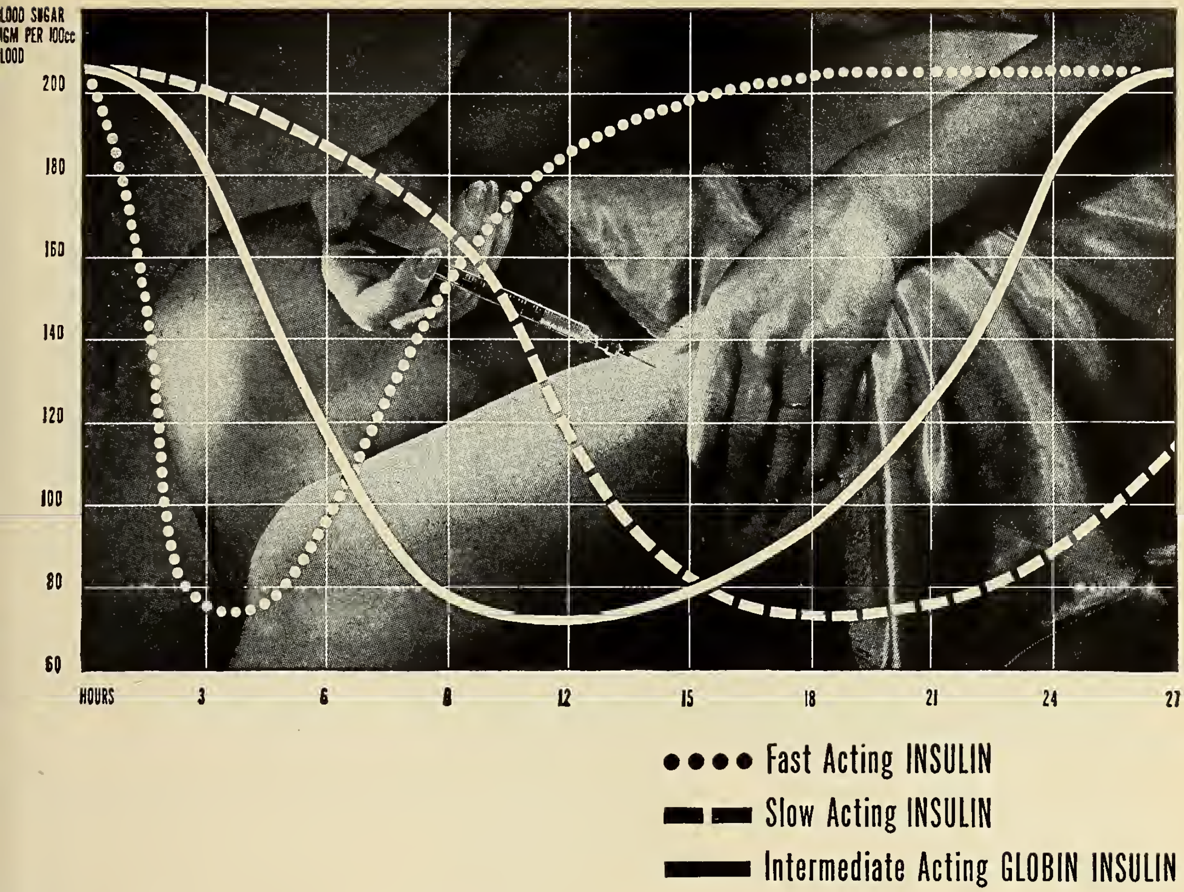
Mrs. Robert S. Forbes has been honored for the excellent work she has done with the Red Cross.

These days each meeting carries with it the excitement of welcoming back those members who have been away so long while their husbands were in the service.

Stearns-Benton Counties

Mrs. R. N. Jones, St. Cloud, was hostess to her Auxiliary on February 12. She gave a report of the State Board meeting held at the Radisson Hotel, January 26. Mrs. J. C. Buscher, representing the Auxiliary, attended the School for Cancer Control at the Continuation Center.

(Continued on Page 372)



Today, there are 3 types of insulin . . .

THE PHYSICIAN now has a new intermediate-acting type of insulin with which to treat his diabetic patients—'Wellcome' Globin Insulin with Zinc. Originally there was only quick-acting, short-lived insulin. Then came a slow-acting, long-lived form. And now with Globin Insulin he has a moderately rapid-acting agent which persists for sixteen hours or more, enough to cover the period of maximum carbohydrate intake. This activity is sufficiently diminished by night to minimize nocturnal reactions. Physicians will do well to consider the advantages of this new third insulin for their diabetic patients.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties.

Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in the Wellcome Research Laboratories, Tuckahoe, New York. U. S. Patent No. 2,161,198. Available in vials of 10 cc., 80 units in 1 cc., and vials of 10 cc., 40 units in 1 cc. Literature on request. 'Wellcome' trademark registered.

Dr. and Mrs. J. B. Gaida of St. Cloud announce the birth of a son, Joseph Aubin, at St. Cloud Hospital. Mrs. Gaida is president of the Auxiliary.

Upper Mississippi

The Brainerd doctors and their wives entertained the Upper Mississippi Auxiliary and Medical Society at The Brainerd on February 9.

Washington County

Mrs. R. J. Josewski of Oak Park, Stillwater, was hostess for the Auxiliary on February 12. Nine members were present.

MINNEAPOLIS SURGICAL SOCIETY

(Continued from Page 360)

Discussion

DR. EARL HENRIKSON: I would like to ask one question. You mentioned one screw that broke. Have you had any others break? These screws are not very strong. There is a lot of tension on them in muscular people. I have seen two that broke and I wonder if you know about what per cent do break.

DR. KENNETH JENSEN: I would like to ask, have you had any recurrences of the acromio-clavicular dislocations after the screw was removed in six to eight weeks?

DR. ROLLA STEWART: Regarding Doctor Henrikson's question: I do not know what percentage of the patients broke the screw. I tried to get all the patients back for follow-up x-rays but could locate only a few. I allowed these patients free use of the arm following surgery and discovered it was abducting the arm beyond 90° that broke the screw. Toward the latter part of this work, I advised the patients to refrain from abducting the arm beyond a 90° angle and to refrain from heavy lifting. The arm should be kept in a sling for about six to eight weeks and then the screw should be removed and free use of the arm allowed. Bosworth devised a larger screw, but this requires a drill hole through the clavicle about ¼ inch in diameter. Any screw similar to vitallium is large enough to hold, providing the patient uses the above precautions.

Regarding Doctor Jensen's question: I have not been able to follow that.

In Memoriam

HERBERT BURR BAILEY

Dr. Herbert B. Bailey of Fairmont died on February 11, 1946, of coronary thrombosis.

He was born February 2, 1883, at Jackson, Minnesota. His grandfather, Major Hiram S. Bailey, was for a time during the Civil War the commanding officer at Fort Fairmont.

Dr. Bailey received his M.D. degree from the University of Minnesota in 1913, and served an internship in the Minneapolis General Hospital in 1913-14. In 1915 he located at Ceylon, Minnesota, where he had an extensive practice before moving to Fairmont in 1934. In 1937 he established his own private hospital, conducting it until war shortages forced its discontinuance.

He was a member of the Blue Earth Valley Medical Society, the Minnesota State and American Medical Associations. He was a member of the Methodist Church and an ardent Mason. He was fond of hunting, fishing and travel and was active in civic affairs.

In 1913 Dr. Bailey married Sena G. Husby, who survives. A son, Dr. Robert B. Bailey, recently returned from service in the Army. His daughter, Helen Jane (Mrs. John M. Sunderson), also survives.

RICHARD W. CRAGG

Dr. Richard W. Cragg, who was with the Mayo Foundation from 1932 until July 1, 1942, when he entered active service in the Navy, died of coronary occlusion February 18, 1946, at his home at Vallejo, California.

Born December 14, 1905, at Cincinnati, Dr. Cragg received the degree of B.S. in 1926 and of M.D. in 1931 from the University of Cincinnati.

He entered the Mayo Foundation as a Fellow, October 1, 1932, and became assistant professor of pathology of the Mayo Foundation in 1941.

In service, Lieutenant Commander Cragg was pathologist at the Naval Hospital at Corona, California. He was then assigned to duty at the Naval Advance Base Training Section at San Bruno, California, and was later made chief pathologist at the Naval Hospital at Mare Island. His entire service to the Navy was performed with outstanding ability and skill, and he gave unstintingly of his time to many civilian activities at Vallejo.

ROBERT S. FORBES

Dr. Robert S. Forbes of Duluth, Minnesota, passed away April 9, 1945, at the age of fifty-eight. He was born in Saint Paul, July 8, 1886, attended Central High School in Duluth, and, after taking two years of premedical work at the University of Minnesota, graduated from the medical school of the University of Pennsylvania in 1910. He interned at the St. Christopher and Presbyterian Hospitals, Philadelphia, from 1910 until

ROBERT S. FORBES

(Continued from Page 374)

1913. In 1922 he took postgraduate work at the Northwestern Postgraduate School, and in 1925 at Vienna.

He was a member of the St. Louis County Medical Society, the Minnesota State and American Medical Associations, and the American College of Surgeons. He was a Scottish Rite Mason and member of the Shrine, and belonged to the Duluth Athletic Club and the Northern Country Club.

Dr. Forbes is survived by his widow, a daughter, Betty, and one brother, Mason M. Forbes of Carmel, California.

T. J. GAFFNEY

Dr. T. J. Gaffney of Lakeville, Minnesota, died November 27, 1945. Born in Minneapolis August 7, 1873, he obtained his M.D. at the University of Minnesota.

After practicing in Minneapolis a year or two he married Madeline Keller of Minneapolis and moved to Lakeville. He is survived by his widow, a brother John and a sister Mary, both of Minneapolis.

EDWIN LESLIE GARDNER

"The life of the dead consists in being present in the minds of the living."—Cicero.

Dr. E. L. Gardner died at his home January 29, 1946, at the age of fifty-nine years, following a two-year illness.

Edwin Leslie Gardner, son of William C. and Eva Gardner, was born August 2, 1886, in Jacksonville, Illinois. His high school education was received at Belmont Military Academy, Belmont, California. He entered the University of Minnesota in 1906, and after two years in the College of Science, Literature, and Arts, entered the Medical School, and was graduated in 1912. He was a member of Nu Sigma Nu, and Alpha Omega Alpha. He held first rank in a class of thirty, and was awarded the Bell prize in physical diagnosis. He served an internship at the Elliott Memorial Hospital and subsequently became assistant to Dr. J. W. Bell, after which he started his career in his chosen specialty—internal medicine.

His society memberships included: Hennepin County Medical Society (president 1930), Minnesota State Medical Society (editing and publishing committee of Minnesota Medicine), American Medical Association, Minnesota Pathological Society (president), Minneapolis Clinical Club (president), Minnesota Academy of Medicine (secretary), Minnesota Society of Internal Medicine (president), American College of Physicians. He was a member of the faculty of the University of Minnesota Medical School, and was attending physician at the Minneapolis General Hospital from 1914 to 1926.

At various times he was on the staff of Glen Lake Sanatorium, St. Mary's, Eitel, Asbury and Northwestern Hospitals. He was associated with Drs. L. S. Ylvisaker,

(Continued from Page 376)

Robert Kennecott, Paul Rowe, Lewis Daniels, Willard White, Charles A. Hallberg, R. S. Ylvisaker, and the writer. He was a member of Hennepin Avenue Methodist Church, the University Club, and the Professional Men's Club.

He was much the same, both as an undergraduate and as a practitioner, always serious minded, and with a singleness of purpose. Had he been born a few decades earlier he would have been known as a pioneer, possessing that industry and diligence characteristic of the self-made man. His secret of life was work. It was a habit so ingrained that it brought him the respect of his teachers and confreres, and a large clientele. When latterly he took up the avocations of photography and music he followed these in the same arduous way that he applied to medicine. In fact, it is not only conceivable but more than likely that this not unmixed virtue contributed to his demise at an earlier time than would otherwise have been so.

In the words of Wm. Osler: "Work not only has been the touchstone of progress but it is the measure of success in everyday life."—T. A. PEPPARD, M.D.

PROSPER ERNEST SHEPPARD

Dr. Ernest Sheppard, for fifty-three years a practicing physician in Hutchinson, Minnesota, passed away February 28, 1946, in his eighty-third year.

Prosper Ernest Sheppard was born at Cannon Falls, Minnesota, March 10, 1862. When he was four years old his parents moved to Lake Allie, Renville County, where he received his early schooling.

Later he attended school in Hutchinson and then at Mankato, where he graduated from high school. He then enrolled in the University School of Medicine from which he graduated in 1891.

His first practice was in the town of Waconia, Carver County, in the year 1891. In 1892 he was united in marriage with Miss Gertrude Walker of Mankato, who died in 1895 leaving an infant daughter Agnes (now Mrs. F. L. Sheppard).

In 1892 he gave up his practice at Waconia and came to Hutchinson where he has since resided and practiced medicine with the exception of a year of leave in 1902-1903, during which he made a trip around the world, with a stop-off in foreign medical schools for postgraduate work.

In 1910 he was united in marriage to Miss Grace Goodnow, daughter of one of Hutchinson's pioneer families. To them were born two sons: Dr. Charles G. Sheppard and Warren Ernest Sheppard. Dr. Sheppard was a member of the McLeod County Medical Society and the Minnesota State and American Medical Associations.

Dr. Sheppard is survived by his widow, his daughter Agnes, his two sons and three grandchildren.

Of General Interest

Dr. John B. Erich, of the Mayo Clinic, was guest speaker at the March meeting of the Cerro Gordo County Medical Society held in Mason City, Iowa.

* * *

Dr. Vincent Ryding, of Minneapolis, has entered practice at Howard Lake, where he has leased the offices recently vacated by Dr. David H. Rolig.

* * *

Dr. Lealdes McK. Eaton, of the Mayo Clinic, has been on a clinical trip which included visits to the Johns Hopkins Hospital in Baltimore and the Edgewood Arsenal, Maryland.

* * *

Dr. and Mrs. Byron O. Mork, Jr., of Worthington, spent March and part of April vacationing in and around Santa Monica, California, where they went by plane.

* * *

Dr. Donald Houston has returned to his practice at Park Rapids from three and a half years in the Navy. Dr. Houston, a lieutenant commander, was on duty in the South Pacific for two years.

* * *

Dr. Robert Ramsey is associated in practice with Dr. Frank E. Burch at 424 Hamm Building, Saint Paul, following his discharge from the Royal Canadian Air Force, in which as squadron leader he acted as consultant in ophthalmology.

* * *

Dr. Gerald Knutson, formerly in practice at Thief River Falls, will open offices in Hallock as soon as he can secure suitable quarters. At the time of his induction in the Army Medical Corps Dr. Knutson was located at Greenbush.

* * *

Dr. Robert Demo, who was in residence at the Rochester General Hospital when inducted into military service, is now associated with the Surgical and Medical Clinic at Albert Lea. Dr. Demo was on duty in the Pacific Theatre for twenty-eight months.

* * *

The Veterans Administration has announced that Dr. Ralph Ghormley, orthopedic surgeon at the Mayo Clinic, has accepted the position as head of the orthopedic surgery section, professional services division of the Veterans Hospital in Minneapolis.

* * *

Dr. Everett R. Youngren is constructing a new medical center in the Payne Avenue district in Saint Paul. Consisting of fifteen rooms, it will include a department for tonsillectomies, dental facilities and the latest x-ray and diagnostic equipment.

* * *

Dr. Walter C. Alvarez, of the Mayo Clinic, has been in Hartford Connecticut, where he gave two addresses before the Hartford Medical Society. Dr. Alvarez' subjects were "Small Usually Unrecognized Strokes—a Common Disease," and "What is Wrong with Dispeptics whose Findings are All Negative?"

* * *

Dr. H. F. Schrockenstein of Saint Paul has received his discharge from the Navy, where he served as a lieutenant commander at the Special Augmented Hospital No. 4 on Okinawa. He is at present taking a course in Basic Sciences at the University of Minnesota Medical School.

* * *

Dr. Frank Adair, Saint Paul, who as a lieutenant commander in the Navy, served for twenty months in the Pacific Theatre and a later assignment in San Diego, California, was discharged on January 18, 1946. Dr. Adair has opened offices in the Lowry Medical Arts Building, where he will specialize in diseases of the eye, ear, nose and throat.

* * *

Dr. Elmer Paulson, who has been in the X-ray Department of the Army Hospital at Portland, Oregon, for the past three and a half years, has been discharged and has resumed his practice at Elbow Lake in association with Drs. Lester and E. Lillian Parsons. Just prior to his release from service, Dr. Paulson was promoted to the rank of major.

* * *

Dr. Arthur J. Henderson, of North Saint Paul, has been appointed deputy coroner for North Saint Paul and immediate vicinity by Dr. Carl A. Ingerson, coroner of Ramsey County. Previously, when the services of a coroner were required in the community, it was necessary to call one from either Saint Paul or White Bear.

* * *

Dr. Edward F. Burch, Saint Paul, has returned from service and has resumed the practice of ophthalmology in association with his father, Dr. Frank E. Burch, at 424 Hamm Building, Saint Paul. During his service, Dr. Burch was stationed at O'Reilly General Hospital, Springfield, Missouri, where he was executive officer and eventually commanding officer with the rank of colonel.

* * *

Discharged after forty-four months of service, Dr. Edward Colp, a commander in the Navy, has resumed his medical practice in Robbinsdale, with temporary offices at 4197 West Broadway. Dr. Colp was in active duty in the New Hebrides, South Pacific, for twenty-two months. During his final months of service he was senior medical officer at Wold-Chamberlain Field.

McKesson Waterless Metabolar

This new basal metabolism apparatus incorporates all the desirable features of modern scientific diagnostic equipment. Completely new and modern in design, it is totally enclosed and beautifully finished in porcelain and chrome to fit in perfectly with the most modern hospital clinic, or office appointments.

The technique of operation is simple . . . direct . . . accurate. It is guaranteed for accuracy and service with no reservation other than rubber parts not including the bellows, which is unconditionally guaranteed for five years. A waterless unit, it is built to give years of satisfactory and trouble-free operation. An automatic calculator limits the mathematical procedure to one calculation.

Complete information and price will be furnished upon request. Write for descriptive booklet No. M186-446. Give voltage and cycle of electric current.

Dr. Hjalmar E. Mortensbak, who took over Dr. Howard A. Vogel's practice in New Ulm, while the latter was in military service, has moved with his family to Great Falls, Montana, where he has purchased the practice of Dr. Fred Andrews, now retired. Dr. Mortensbak was a member of the Nicollet Clinic in Minneapolis just prior to his going to New Ulm and had formerly practiced at Hanska for about six years.

* * *

Under the sponsorship of the American Committee for Yugoslav Relief, Dr. Robert Neubauer, a former medical officer in the Yugoslav Army and a member of the Yugoslav Red Cross Delegation, addressed medical students and staff at the Minnesota University on March 4. Dr. Neubauer, who worked in the underground hospitals and organized medical services for partisan fighters during the war, discussed medical problems in Yugoslavia.

* * *

Shortly before the expiration of his terminal leave on March 1, Dr. Joseph Berkson, head of the Section on Biometry and Medical Statistics at the Mayo Clinic, was awarded the Legion of Merit for "having contributed immeasurably to the advancement of medical statistics in developing new methods of presenting and interpreting statistical data as applied to Army Air Force matters." Dr. Berkson, with the rank of colonel, served as chief of the Statistics Division, Office of the Air Surgeon, Headquarters Army Air Forces.

* * *

Dr. James R. Weir, formerly of Minneapolis, has moved with his wife and two small children to Goodhue, where he has opened offices for general practice. Dr. Weir is a graduate of Wheaton College, Illinois, where he took his B.A. and the University of Illinois Medical School. He interned at St. Barnabas Hospital in Minneapolis, and for the past eighteen months was associated with Dr. Owen F. Robbins, Minneapolis, specializing in obstetrics.

* * *

Dr. Charles F. Brigham, Jr., who before joining the Army Medical Corps in July, 1942, was in practice in Saint Paul, is now associated with the St. Cloud Clinic.

Dr. Brigham is the son of Dr. C. F. Brigham, of St. Cloud. He graduated from St. John's University in 1937 and the University of Minnesota Medical School in 1941. While in the Army he served practically all of the time at 262nd General Hospital and the Gorgus Hospital in the Panama.

* * *

Dr. Anthony H. Field, a captain in the Army Medical Corps for twenty-three months, has returned to his position as physician and surgeon at the Sanford Hospital in Farmington. Dr. Field was in England

with the 109th Hospital unit for eleven months. Returned to this country in June, 1945, he was assigned to the Separation Center at Camp Grant, Illinois, where he served until his discharge on January 16, 1945. Five days later he had resumed his practice in Farmington.

* * *

Following the arrival in Aitkin of Dr. F. C. Closuit, Dr. Irvin L. Mitby's new assistant, Dr. Mitby left for Minneapolis for several weeks' work in diseases of the eye under Dr. Robert Tracht at the University of Minnesota School of Medicine.

Dr. Closuit, who was recently discharged from the Army Medical Corps with the rank of major, graduated from the University in 1941.

Mrs. Closuit, a medical technician before her marriage, will have charge of the laboratory and x-ray work in the office.

* * *

After forty years of practice in Harmony, Dr. Charles M. Tierney has sold his practice to Dr. Alfred H. Wolf, of Minneapolis, and is retiring because of ill health.

Dr. Wolf was born in Chatfield, but his youth was spent in La Crosse, Wisconsin, where his parents moved when he was two months old. He is a graduate of the University of Wisconsin and the Medical School of the University of Pennsylvania. He interned at St. Mary's Hospital in Minneapolis and was inducted into the Army Medical Corps in October, 1944.

* * *

Dr. Donald Hastings, successor to Dr. J. Charnley McKinley as chairman of the Department of Psychiatry and Neurology at the University of Minnesota, assumed his duties on April 1. Dr. Hastings, an alumnus of the University of Wisconsin, was chief psychiatrist of the Eighth Air Force during the war. Formerly, he was a member of the staffs of the University of Pennsylvania Medical School and the Women's Medical College in Philadelphia.

Dr. Burtrum C. Schiele, psychiatrist, and Dr. Abe B. Baker, neurologist, are Dr. Hastings' associates.

* * *

A two-day institute on Cancer Education was held in Duluth on March 12 and 14 under sponsorship of the Duluth Division of the Minnesota Cancer Society, the Duluth Community Health Committee and the University of Minnesota Extension Division.

Dr. Fredolph H. Magney, of Duluth, presided at the first meeting at the Hotel Spalding, when Dr. William A. O'Brien, professor of preventive medicine at the University of Minnesota, spoke on "The Nature of Cancer."

There were two sessions on March 14; one at the Hotel Spalding at two o'clock in the afternoon and the other at the Chamber of Commerce at eight P.M.

Dr. Philip A. Kees, formerly of Saint Paul, a graduate of the University of Minnesota, where he took his science degree, and of the Pennsylvania University Medical School, has resumed his practice at Springfield, Massachusetts, after four years in the Army. Dr. Kees also did research and studied orthopedic surgery at the Mayo Clinic. His war service included duty as chief of surgery at air base hospitals, orthopedic surgeon at an evacuation hospital and operating surgeon of a paratroop combat team. He was wounded three times and was awarded the Purple Heart with bronze clusters, the Bronze Star and the Silver Star.

* * *

After more than four years in the Navy, Dr. James P. O'Keefe has engaged in the practice of surgery and medicine at St. Cloud in association with Dr. Francis [illegible]. Schatz.

Dr. O'Keefe is a graduate of St. John's University and Marquette Medical School, where he finished in 1940, when he was assigned to the Naval Hospital at Baltimore Maryland, and later to Birmingham, Alabama. From there he was sent to Pensacola, Florida, where he graduated as a flight surgeon. In the closing months of the war he was attached to a B-25 Marine Bombing Squadron in the Pacific.

* * *

After fifty years of service to Balaton and the surrounding community, Dr. Charles Germo has closed his offices and has written *finis* to his medical practice there.

Dr. Germo opened his offices in Balaton in 1895 shortly after graduating from the University of Minnesota Medical School and, except for a brief interval when he was in the armed forces during World War I, he has been in continuous practice there ever since. Beginning when he was twenty-three, the story of Dr. Germo's practice is a saga of the age of oxen, which were in common use, when he first went to Balaton, through the machine age into the era of airplane transportation.

Dr. and Mrs. Germo are closing their home and moving away from Balaton.

* * *

Speakers at the annual conference of the thirty-four county and district medical societies of the Minnesota Medical Association held in Minneapolis on March 2 included Dr. John R. Paine, of the staff of the University Hospital and Dr. Richard Hullseick, of Saint Paul, who talked on "Medical Care for Veterans"; Dr. Arthur H. Wells, pathologist, Duluth, Dr. Berton J. Branton, Willmar, and Dr. Alfred W. Adson, of the Mayo Clinic, and Dr. Albert J. Chesley, secretary of the Minnesota State Health Department, who explained the distribution of the blood plasma which was recently presented to the State by the American Red Cross. The return of Dr. Joseph Emon to his practice in Farmington has enabled his brother and associate, Dr. Albert J. Emon, to get away for a much-needed vacation, which he is spending in Oklahoma and California.

Dr. Joseph Emon, a major in the Army Medical Corps, was in service for fifty-one months. His first assignment was at Ft. Ord, California, where he had charge of a medical clearing station for eleven months. From there he was sent to Alaska as commanding officer of the station hospital there and also post surgeon at Bethel and Seward. Returned to the States in February, 1944, Dr. Emon was placed in charge of the Medical Technicians' School, Billings General Hospital, Ft. Benjamin Harrison, Indiana. Later he was assigned to Camp Atterbury Convalescent Hospital as battalion surgeon, where he remained until his terminal leave.

* * *

Recent returnees from military service to the Mayo Clinic include Dr. S. B. Lovelady, Dr. Hugh R. Butt, and Dr. Lucian A. Smith.

Dr. Lovelady, a lieutenant colonel in the Army, entered service on August 4, 1942. He was executive officer of the 182nd General Hospital in England for approximately eighteen months, when he was returned to this country and assigned to Camp Grant, Illinois, where he was in charge of officers of the medical division of the separation center. Dr. Lovelady is a consultant in obstetrics and gynecology at the Clinic.

Dr. Smith, a major in the Army, was inducted in June, 1943. He served overseas as a general medical officer with the 237th Station Hospital in New Guinea and Luzon, and was awarded the Bronze Star for meritorious service.

Dr. Butt, a lieutenant commander in the Navy, entered service on July 1, 1942. He was stationed at the naval hospital at Corona, California, for two and a half years before serving overseas on the hospital ship, *USS Repose* for nine months in the China Theatre. Although Dr. Butt's terminal leave did not expire until April 12, he resumed his work at the Clinic six weeks or more ago.

Both Dr. Smith and Dr. Butt are in the general medical section at the Clinic.

* * *

Dr. Winchell McK. Craig, the only rear admiral in the USNR Medical Corps, whose terminal leave expired on April 8, has resumed his work in neuro-surgery at the Mayo Clinic. Dr. Craig is also a professor of neuro-surgery at the Mayo Foundation Graduate School at the University of Minnesota.

For the six months following his entrance into active service on December 26, 1941, when he was made commander of one of the two units organized at the Mayo Clinic, Dr. Craig was stationed at the Naval Hospital in Corona, California. From there he was

ransferred to the National Naval Medical Center in Bethesda, Maryland, where he served as chief of surgery until September, 1945.

Dr. Craig made three overseas special missions. The irst took him to England, where he landed on D-Day une 6, 1944. As consultant surgeon to the naval forces n the ETO, he made an inspection tour of facilities n England, France and the Normandy peninsula. In he fall of 1944 he was sent by the Surgeon General of he Navy to the Pacific Theatre.

In September and October, 1945, Dr. Craig made a 75,000-mile flight throughout the Pacific, covering Pearl Harbor, Guam, the Marshall Islands and the Philippines on a survey to determine postwar requirements n medical activities and medical education in the Navy. t was the completion of this mission which brought he promotion to rear admiral, the first time this rank has ever been conferred on a Medical Reserve officer. From November until his release from military duty, Dr. Craig was in the Professional Division of the Bureau of Surgery and Medicine in Washington, D. C., where he was engaged in establishing postwar graduate training in naval hospitals.

* * *

The Hennepin County Medical Society has announced he return from military service to practice of the ollowing physicians:

Dr. Nathaniel J. Berkwitz, psychiatrist, with offices n the Medical Arts Building. A lieutenant colonel, Dr. Berkwitz had been in the Army Medical Corps since 942.

Dr. David A. Burlingame has resumed his practice n his offices in the Medical Arts Building. A major n the Army, he entered service in November, 1942.

Dr. S. Paul Ehrlich has returned to the practice of urgery with offices in the Medical Arts Building. A ommander in the Navy, Dr. Ehrlich had twenty-nine months of service.

Dr. Joseph C. Giere, urologist, has reopened his offices in the Metropolitan Bank Building. Dr. Giere was nducted into service in October, 1943.

Dr. Fred C. Holzapfel has resumed general practice t 1101 West Broadway. Dr. Holzapfel had been in ervice since March, 1944.

Dr. Gerald M. Koepcke has resumed his practice in diseases of the eye, ear, nose and throat, at 801 Physicians and Surgeons Building. With the rank of commander Dr. Koepcke was in the Navy for thirty months.

Dr. Frank Larsen has opened his offices for general practice at 1527 East Lake Street. A lieutenant commander in the Navy, Dr. Larsen entered service in October, 1942.

Dr. Henry Michel has resumed general practice with offices at 5004½ Xerxes Avenue. A captain in the Army, Dr. Michel was inducted into service in January, 1943.

Dr. John T. Pewters, obstetrician, has returned to his offices in the Donaldson Building. A major in the Army, Dr. Pewters was in service for thirty-six months.

Dr. Robert Priest has resumed his practice in dis-

eases of ear, nose and throat in his offices in the Medical Arts Building. Dr. Priest entered service in August, 1942, and was a major in the Army.

Dr. Melvin B. Synikin, has re-opened his offices in the Medical Arts Building for the practice of obstetrics and gynecology. A captain in the Army, Dr. Synikin entered service in August, 1943.

HOSPITAL NEWS

Dr. Francis Fowler Callahan, superintendent of the State Tuberculosis Sanatorium at Walker, was the guest speaker at the annual meeting of the Isanti County Public Health Service held at Stanchfield on February 5.

* * *

Our Lady of Mercy Hospital in Alexandria is one of the seventy-five hospitals listed as approved in the twenty-eighth annual survey made by the American College of Surgeons.

* * *

St. Olaf's Hospital in Austin has engaged C. W. Hildreth as business manager. Mr. Hildreth was recently discharged from military service, where he was assigned to the Medical Administrative Corps.

* * *

Dr. John Edward Power was elected chief of staff of St. Mary's Hospital in Duluth at the annual staff dinner given by the Sisters of St. Benedict on February 7. Other department chiefs chosen at the same time were: Dr. N. R. Gowan, chief of staff elect; Dr. Frank Cole, anesthesiology; Dr. Anthony J. Spang, staff secretary; Dr. John A. Winter, eye, ear, nose and throat; Dr. Richard Bardon, medicine; Dr. Russel J. Moe, obstetrics; Dr. Mark H. Tibbetts, orthopedics; and Dr. Murdoch A. Nicholson, orthopedics.

* * *

Dr. Virgil E. Quanstrom was elected chief of staff of St. Joseph's Hospital, Brainerd, at the annual meeting and dinner given by the Sisters of St. Benedict. Dr. William E. Fitzsimons was made vice chief, and Dr. John Thabes, Jr., secretary and treasurer of the staff.

Guest speakers at the dinner were Dr. Keith R. Fawcett, of the Duluth Clinic, who discussed "Sinus Thrombosis" and Dr. John Rukavina, of the staff of St. Mary's Hospital, Duluth, who spoke on "Plasma Protein."

* * *

Dr. Harry Johnson was elected president of the staff of St. Andrew's Hospital in Minneapolis at the annual staff election. Dr. Johnson recently returned from two years' military service in the South Pacific. Dr. J. S. Blumenthal was made vice president, and Dr. Ronald E. Risch secretary-treasurer.

Dr. Irving Preine was elected secretary-treasurer of the Board of Trustees of the hospital at their meeting on the same date.

* * *

Under a Veterans Administration plan the Veterans' Hospital in Minneapolis will be staffed with 146 physicians, seventy-eight of whom—members of the faculty of the University of Minnesota Medical School—will officiate in consultant capacity. Actual care will be the responsibility of the other seventy-eight, all graduate doctors from the University, who will work full time under a fellowship system. Consultants will make regular periodic visits to the hospital and will be on call in case of emergencies. So far, twenty-two consultants and senior consultants and seven fellows have been approved.

* * *

Dr. Miland E. Knapp was elected chief of staff of St. Barnabas Hospital, Minneapolis, at the annual meeting of the medical staff. Dr. Knapp is president of the American Congress of Physical Medicine and Clinical Professor of Physical Medicine at the University of Minnesota.

Other officers chosen at the same time were Dr. Joseph T. Spano, vice chairman; and Dr. William E. Proffitt, secretary. Dr. Carl O. Rice, retiring chief of staff, and Dr. H. D. Giessner were appointed members of the executive committee.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE CARE OF THE AGED (GERIATRICS). Malford W. Thewlis, M.D. 5th ed. 500 pages. Illus. Price $8.00. St. Louis: C. V. Mosby Co., 1946.

The growing interest in the subject of geriatrics is attested by the circumstance that this very worth-while book from an author well qualified to write it is now in its fifth edition. Comparing this with the third edition one sees that there has been some fruitful concentration: the number of chapters has been reduced from thirty-eight to thirty-three and the illustrations from forty-four to thirty-five. The author introduces some new terms: "Geratology": geros, old age; logos, study thereof. He would thus introduce a term somewhat distinct from "Gerontology," the study of the aging process itself. Another Greek root is used to cover the field of hygiene and associated features. Thus the term "Gerocomia" is coined. Under this heading, the author outlines very interesting items leading up to the general cultivation of habits and hobbies.

In Part IV the author then systematizes the difficulties of the aged in terms of organs, both anatomically and physiologically. After the various chapters some of the older references are left out and certain others added. I approve under the dietary schedule the abandonment of many listed menus. Geriatric nursing, in Chapter XII, is especially well outlined.

In any book for review one looks for items yielding what we may call "challenges and chuckles." For example, in a very good chapter on the relationship between disorders, diets and obesity, there is this significant statement: "In health there is the greater danger from the attendance upon the individual of a good cook than of a poor physician when he is sick"—or, at least, that is the general idea. Then the author comments upon the number of elderly women who smoke equally as vigorously as the men, and who are inclined during wakeful periods to get up and stumble around, seeking the sedation of a smoke. One elderly man set fire to his surroundings three times, but still insisted on smoking the weed.

The author has very sane ideas in regard to focal infection and the folly of wasting many useful teeth, just because the aging person accumulates cleassis squeaks. The book does not stress sufficiently protein sufficiency and simpler ways to maintain it in the extremity imposed by chronic illness, mental decay, malignancy and gastro-intestinal imbalance. I heartily recommend the book.

E. S. Tuohy, M.D.

In the distressing disturbances of the menopause, both natural and surgical, administration of the pure, crystalline estrogen THEELIN effectively "tides the patient over" this transitional period until endocrine readjustment occurs. It is also indicated in disorders due to estrogenic deficiency, such as vaginitis, kraurosis and pruritus vulvae.

Theelol Kapseals are available for treatment of the milder menopausal symptoms and for maintenance between injections. Theelin Suppositories, Vaginal, are particularly well adapted for the treatment of gonorrheal vaginitis.

THEELIN

Theelin in Oil is available in ampoules of 0.1, 0.2, 0.5 and 1.0 mg., in boxes of 6 and 50. Theelin, Aqueous Suspension, in 2 mg. ampoules, in boxes of 6 and 25. Theelol Kapseals, 0.24 mg., in bottles of 20, 100 and 250. Theelin Suppositories, Vaginal, 0.2 mg., in boxes of 6 and 50.

Calm climacteric

With the aid of Amniotin, a *natural* estrogen, the menopause can become the normal transition it should be. Vasomotor symptoms are controlled; real and imagined fears calmed; and a new feeling of well-being is born. A highly purified complex mixture of estrogens derived from natural sources, Amniotin has been used by physicians with safety and economy for 16 years. It is available in parenteral, oral and intravaginal forms, standardized in International Units.

In the Nutrition Problems of
CHRONIC CHOLECYSTITIS

Because of the low fat intake which is frequently necessary, many foods and beverages are denied the patient with chronic gall bladder disease. If dietary curtailment becomes too drastic, however, nutritional deficiencies are apt to develop, adding further complications and physical discomfort.

The delicious food drink prepared by mixing Ovaltine with skim milk provides many of the nutrients considered essential in hepatobiliary disease, without appreciably increasing the fat intake. Its biologically adequate protein, readily utilized carbohydrate, B complex and other vitamins, as well as essential minerals aid in satisfying the need for these nutrients. This readily digested food supplement makes a nutritionally excellent as well as delicious component of the extra feedings which are frequently required in the management of chronic cholecystitis.

CAMP

Orthopedic Support FOR Chronic Low Back Pain

Patient of intermediate type-of-build (skeleton indrawn)

This lumbosacral support is specifically designed to limit the range of the lumbar spine bending when either the framework or soft tissues of the low back are the seat of injury or disease. Effective support is given the gluteal region, the lumbar spine and the sacro-iliac and lumbo-sacral joints. The adjustment about the pelvic girdle prevents undue pressure of the upper adjustments and yet the presence of the center adjustment gives relief and comfort to the patient. Provision is made for reinforcement with aluminum uprights when indicated.

PROTEIN
and the Dietary of Kidney Disease

The fundamental concept, that nutritional requirements must be met in disease as well as in health, holds especially true in renal disease.[1] Because many affections of the kidney involve excretion of blood albumin via the urine, the intake of protein in former years was curtailed in a futile attempt to stem the loss of protein.

Modern nutritional science has emphasized the necessity for maintaining nitrogen balance even in the face of the severe albuminuria characteristic of lipid nephrosis.[2] Not only must the basic nitrogen requirements of the organism be met, but the urinary loss must be compensated for as well.[3] Only when this adjustment of protein intake is made can the plasma albumin be restored to normal levels and the associated edema overcome.

Meat is an excellent source of protein in the management of nephritis and nephrosis, not only because of the high percentage of protein contained, but especially because its protein is of highest biologic quality, applicable for every protein need.

WATER-SOLUBLE
Estrogens
ACCEPTED
AMERICAN MEDICAL ASSN.
Council on Pharmacy and Chemistry

Estrogens are excreted by the kidney not as free chemical compounds but as *conjugates.* In this natural form, the equine estrogens . . . estrone, estradiol, equilin, equilenin, and hippulin . . . are present as water-soluble sulfates which are highly active when administered orally. Under hydrolysis, however, the conjugation is destroyed and the estrogens are converted to free chemical compounds which are water insoluble and comparatively inactive orally.

In "PREMARIN", the equine estrogens are carefully protected against hydrolysis to preserve their highly desirable characteristics. "PREMARIN", therefore, is *water soluble* and orally effective, making possible the control of menopausal symptoms with tablet or liquid medication.

An extensive bibliography on "PREMARIN" attests to its high therapeutic effectiveness, its comparative freedom from toxicity, and to the fact that treatment is usually followed by a general feeling of well-being.

Doctor's nightcap in baby's bottle

When the doctor prescribes 'Dexin' brand High Dextrin Carbohydrate, it is like a soothing nightcap for both himself and his little patients. Because of the high dextrin content, (1) intestinal fermentation with its tendency to colic and diarrhea is diminished, and (2) the formation of soft, flocculent, easily digested curds is promoted. Frantic parental midnight phone calls are less frequent and both the doctor's and the babies' rest are undisturbed.

'Dexin' is readily soluble in either hot or cold milk or other bland fluids, and it is not so sweet as to be unpalatable. 'Dexin' does make a difference.

'Dexin'

HIGH DEXTRIN CARBOHYDRATE

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

For preoperative and postoperative use

Demerol hydrochloride, administered from thirty to ninety minutes preoperatively, relieves much of the surgical patient's apprehension and reduces the amount of anesthetic agent required to obtain a given depth of narcosis. The average preoperative dose for adults is 100 mg. injected intramuscularly, which may be combined with scopolamine or a barbiturate to assure amnesia.

Compared with morphine, Demerol causes considerably less nausea and vomiting, and the danger of respiratory depression is greatly reduced. Unlike morphine, Demerol does not interfere with the cough reflex or the reflexes and size of the pupil. It does not cause constipation, and urinary retention is less than with morphine.

Postoperatively, Demerol is a reliable analgesic in the majority of cases, regardless of the type of surgery or the severity of pain. Patients in the older age group, in particular, respond most favorably to this drug. The average postoperative dose for adults varies from 50 to 100 mg., administered by intramuscular injection or by mouth.

The Abbott Collection

PAINTINGS OF ARMY AND NAVY MEDICINE

Abbott Laboratories is proud to announce that the Abbott Collection Paintings of Army and Navy Medicine is to be shown at the Minnesota State Medical Association meeting in the St. Paul Municipal Auditorium, from May 20 through May 22 and at the Mayo Auditorium in Rochester, from June 7 through June 13. ● Through the cooperation of the United States Army and Navy, seventeen of America's most distinguished artists, commissioned by Abbott Laboratories, were enabled to make this complete pictorial record of Army and Navy Medicine. Armed only with palette and brush the artists risked their lives voluntarily and repeatedly to cover every theater of war where American troops fought. ● It is sincerely hoped that all friends of Abbott will find it possible to attend. Abbott Laboratories, North Chicago, Illinois.

No different instructions needed for the patient—
No difference in therapeutic procedure

Yet All These Advantages

DIGITALINE NATIVELLE—pure crystalline digitoxin—the chief active glycoside of Digitalis purpurea, offers many advantages in the treatment of congestive heart failure, auricular flutter and fibrillation.

Its administration is identical with that of whole digitalis leaf preparations, since one tablet of Digitaline Nativelle (0.1 mg.) is the therapeutic equivalent of 1.5 gr. of standardized whole leaf. Hence no different instructions to the patient are necessary, no greater caution need be observed. One such tablet of Digitaline Nativelle has been found to be the average maintenance dose, to be increased or decreased if necessary.

Because it is pure crystalline digitoxin, the dosage of Digitaline Nativelle is measured by weight, hence unvarying potency is provided. Digitaline Nativelle is absorbed in toto, probably directly from the stomach, making for greater tolerability and virtual freedom from nausea and vomiting due to local irritation.

Digitaline Nativelle also provides the outstanding advantage of rapid, complete digitalization from oral administration. The average digitalizing dose is 1.2 mg., given either at one time or in 2 doses of 0.6 mg. each at a 3- to 6-hour interval. Digitalization is complete in 6 to 10 hours.

Physicians are invited to send for samples, literature and bibliography

the Mop-up

SCRUBBING the operative field with soap and water effectively eliminates most of the bacteria. But before the surgeon makes his incision, he must be certain that the last troublesome enemy is dispatched. Tincture 'Merthiolate' (Sodium Ethyl Mercuri Thiosalicylate, Lilly), 1:1,000, is especially qualified for the "mop-up" detail. When Tincture 'Merthiolate' is applied, many nonsporulating pathogenic organisms are given the *coup de grâce* on contact. Stragglers which dare to rise from a hair follicle or which fall on the operative field from the air are also exposed to the germicidal action of the film of 'Merthiolate' on the skin. The low toxicity of 'Merthiolate' and its compatibility with body fluids recommend it as a safe, reliable skin disinfectant. Tincture 'Merthiolate' is available in leading hospitals and pharmacies everywhere.

MICE, MEN, MALIGNANCY

LEONELL C. STRONG, Ph.D., Sc.D.

Associate Professor of Anatomy, Yale University School of Medicine

New Haven, Connecticut

I WOULD like to take this opportunity of expressing my sincerest thanks to Dean Diehl, to his consulting committee on selection and through them to the Medical School and to the University of Minnesota for giving me the opportunity and honor of being with you this evening, of having my name added to the list of former men who, in the past, have given the George Chase Christian lectures on cancer research and of visiting this great midwestern University. It is not a hasty conclusion that leads me to express the opinion that the name of George Chase Christian, associated with the present Director of Cancer Biology at this University, will live long as a benefactor for the investigation of cancer, that greatest scourge that afflicts mankind at present.

Mankind is living in fear of its own destruction by the use of atomic energy in war. The rising death rate from cancer rarely makes the head lines as does the atomic bomb. Cancer's attack on man is more insidious. We are told by competent statisticians that, unless some advance is made in the control of cancer, by 1960 nearly a third of a million people will die each year from cancer in the United States. It is the broad social principles possessed by such individuals as Mrs. George Chase Christian and other benefactors, the untiring labor of public health officials, visiting nurses and other layworkers in the field, the medical profession and the patient scientist working in the laboratory, that will help in the prevention of such a catastrophic outcome.

We have two sons. One, when he started to talk, said he was "going to be a doctor that put iodine on." The other, that he was "going to be a mouse doctor like daddy is." Now a doctor that puts iodine on is self-evident. But a mouse doctor! At thirty-nine months of age Junior was given a mouse to play with. It was not long before he said, "Look, daddy, this mouse has a cancer. Jumjum going to operate—jumjum going to take cancer off." Some time later I returned to the laboratory and there was Junior, trying to thread a needle with suturing silk. The mouse was still alive, an incision had been made neatly over the cancer, the cancer was gone and a complete record of the operation had been entered into my permanent ledger. I merely use this illustration to introduce the idea that a mouse does develop cancer. This is not an archaic idea. Many medical men still say that cancer is peculiarly a human disease. Only a few years ago I was discussing before a medical group some of my results of producing stomach cancer in mice. The eyebrows were raised and considerable whispering was taking place—so I announced that I had brought several mice with cancer into the room and would be willing to show them after the meeting. One of the skeptics came forward and examined the mice very carefully. I demonstrated the primary site of the cancer in the stomach, its spread into the liver, onto the diaphragm and the peritoneum and down through the belly. I began to see a broad smile come over

---

The George Chase Christian Lecture delivered February 7, 1946, at the University of Minnesota.

The research upon which this lecture is based was supported by grants from The Anna Fuller Fund and The Jane Coffin Childs Memorial Fund for Medical Research.

his face and he volunteered, "You know I had a man that died of stomach cancer last week and he looked just like that mouse."

A few years ago, seven to be exact, a young hyperkinetic anatomist came to New Haven from a large mid-western university. He was shown the many types of tumors and cancers that were being produced in mice. His comment was, "If I weren't a Boy Scout, I would wager that not a man on the faculty of the university from where I come has ever seen a mouse with cancer." And at present, just seven years later, this university is assuming a leading part in cancer research and they are emphasizing the use of the mouse for this work.

But the eastern seaboard was not far ahead of the rest of the United States in experimental cancer research. In the year 1900, spontaneous tumors in mice were so rare that their commercial value was $300. Now the market value is somewhere in the neighborhood of seventy-five cents. The change in supply was brought about, almost exclusively, by the establishment of pure strains of mice by the geneticist, and the only technique employed was the application of the progeny test —that is, the reversal of the old principle of classifying offspring by characterizing parents. Geneticists, knowing that many intrinsic capacities are hidden or recessive in inheritance, wait to see what will show up in the offspring before they classify the parents. This technique employs the genetic principles of hybridization, controlled brother to sister or other restrictive matings, selection and elimination of unfavorable sublines that do not conform to type. You may realize that this new technique deviates considerably from the older one employed by the pioneer in the genetics of cancer susceptibility, Maud Slye of Chicago. She employed the so-called "pedigree system" by which is meant that all descendants of a single cross were kept alive as long as possible and autopsied at the time of their deaths. Thus she was able to produce for the first time a tremendous number of malignant and benign tumors in mice. The newer system of selection and elimination by selective restrictive mating permits elimination of uncontrolled biological or genetic variability thus aiding in placing cancer research on a quantitative basis. As a result of this newer refinement of genetic research, a firmer basis resulted which permitted rapid progress in the study of the nature of cancer to be made. The establishment of the inbred or pure strai mouse made possible many discoveries in the fiel of pure genetics, as well as other contribution outside genetics, such as the detection of th milk influence in adenocarcinoma of the mammar gland in mice that probably never would hav been made or would have been considerably delayed.

Two of these strains are the A and the C_3H These mice have been produced by a continuou restrictive mating, usually of a brother-to-siste or a son back to its own mother for many generations. In the F13 generation after several inbred generations had been produced, spontaneou tumors of the mammary gland began to appear— and further that when the disease had been introduced into the inbred mice for some still unknown reason possibly the introduction of th milk influence of Bittner in a genetically prepared receptive mouse, cancer continued to develop spontaneously in each and every female o each successive generation. The A strain mic also develop spontaneous tumors of the lung i rather high numbers, although here the milk influence does not operate. In the C_3H strain, a similar situation was obtained as far as spontaneous adenocarcinoma of the mammary glan was concerned. The C_3H mice were develope by a continuous selection toward high susceptibility to such tumors. They consequently not onl develop these tumors spontaneously at an earlie age than do female mice of the A strain but als differ in that virgin mice show as high an incidence of breast tumors as do female mice that are used for breeders. But these mice also developed a new characteristic favorable for the investigation of another aspect of cancer in that they possess a very high susceptibility to give rise to tumors induced by chemical means, a wholly unexpected result. We shall have more to say about these induced tumors in a few moments.

We have indicated very briefly some of the advantages of the use of inbred strains of mice. Perhaps it may not be out of place for the individual who developed many of the standard inbred strains and who has used them in quantitative cancer research for nearly thirty years, to point out some of their limitations. In the first place, the inbred mice give rise to very few types of spontaneous tumors. When one enumerates: (1) adenocarcinoma of the mammary gland; (2)

adenocarcinoma of the lung; (3) adenomatous hyperplasia of the stomach; (4) hepatoma; (5) myelogenous; and (6) lymphatic leukemia, the entire list of spontaneous tumors that occur in any degree of frequency has been given. In the second place, these spontaneous tumors, compared to human material (the criteria of malignancy being invasion and ability to metastasize) are not particularly very malignant. Opinion differs considerably, however, upon these points.

While the geneticists have occupied themselves in the development of standard strains of experimental animals, particularly mice, where biological variability has been reduced to a minimum, the organic chemists have also been interested in cancer. Following the lead supplied by observations that chimney sweeps develop a peculiar so-called chimney-sweep's cancer upon a long-continued exposure to soot, the chemists have synthesized a large number of pure chemicals, which when injected into or applied to suitable experimental animals will cause cancer to arise at the site of application. These chemically induced tumors are usually more malignant than the spontaneous ones occurring in animals. They also occur in greater variety depending upon several factors under experimental control, one of which is the site at which the cancer-producing substance has been applied.

We now have before us, therefore, all the experimental techniques necessary for the investigation of cancer. The problem can be stated thus. Can we produce in experimental animals the vast array of very malignant cancers and relatively benign tumors that afflict the human population in ever-increasing numbers? The answer is yes and we shall now proceed to develop this thesis for you, to show the results obtained, to indicate the biological effects of injecting a powerful cancer-producing substance, 20-methylcholanthrene, into mice over a number of generations and to draw some pertinent conclusions.

From immemorial time the mundane egg has been used as a symbol for life. We, therefore, proceed to put the human population into an egg. Man is characterized by great variability when the spontaneous tumors and cancers to which he gives rise are classified. It is also probably true that no two individuals (except identical or monozygotic twins) ever have the same genetic constitution. One component of this extremely variable genetic state, the germ plasm, is made up of innumerable pairs of genetic determiners or factors or genes, each pair of which may exist in three combinations (the homozygous dominant, the heterozygous dominant-recessive and the homozygous recessive) one may realize that the mechanism responsible in part for this great genetic variability has been indicated. A gene is the physical entity within the germ plasm which transfers a characteristic of the parent to its offspring. The characteristic may be either manifest or potential. It is more likely, therefore, that the great display of spontaneous tumors and cancer that man gives rise to may be the result of the great variability of his intrinsic or genetic constitution, influenced by continuous contributions from diversified ancestries.

In contrast to the biological situation found in man, we have, in the production of the inbred mouse, another genetic situation. Here we have, over a period of many generations, by 105 brother-to-sister matings in the case of the A strain referred to previously, eliminated a considerable number of potential grandparents or other more distantly related ancestors, thus preventing many new and old genetic variables from getting into the animal descent. We also have permitted many of the so-called heterozygous or hybrid combinations of unit pairs of genes to reduce variability by becoming pure or homozygous. Eventually a very great number of the possible gene combinations are reduced to uniformity and the animal is called a pure-bred or homozygous animal. The homozygous animal may be said therefore to possess great uniformity in genetic constitution, that is, all animals of a given inbred line have precisely the same genetic constitution. They even exceed the genetic situation found in man only in monozygotic twins. Now the inbred animal shows greater uniformity in every biological characteristic that has ever been measured than do mice belonging to unpedigreed nondescript stocks produced by promiscuous or uncontrolled matings. And this is also true for the three types of tumors, the spontaneous, the transplanted, and the induced that have been made available to cancer investigators. Therefore, this great uniformity of tumor types may very well be due to the great genetic uniformity that mice possess. It is also true that mice of different inbred lines, differ from each other in (1) genetic constitutions and (2) the types of tumors obtained in them.

Now by crossing together two mice belonging to two separate or distinct inbred lines, we may pass in one generation from the homozygous state of the inbred mouse to the heterozygous state. The number of genes that will pass into the heterozygous state through this process of hybridization depends upon the number of divergent or contrasted unit characters that the original homozygous mice possess. It should be readily apparent that if the two parents that produce the so-called F_1 individual were pure for many characters, then all their first generation hybrids will be uniform although heterozygous for many gene-pairs in their genetic constitution. . . . The greater will be the degree of hybridity, the greater the number of different unit characters possessed by the mice of the two ancestral stocks. It has also been ascertained that mice in the heterozygous state are not only uniform in genetic constitution but also in the types of tumors obtained in them: (1) the spontaneous; (2) the transplanted; and (3) the induced.

When we begin to breed heterozygous mice together by any system of restrictive mating we begin the return to the homozygous state—only here the process of return is slow and takes many generations and many years. (Mice produce under the most favorable conditions only four or five generations per year.) No one can say what state of inbreeding mankind is in at present. When one projects backward in time only four or five hundred years, the potential number of parents and grandparents needed to produce you and me, it may be realized that some blood relationship must have existed between some of the parental lines—thus any restriction of the potential total number of grandparents would eliminate some possible intrinsic biological characteristics or variations and thus produce some degree of inbreeding. But really it does not matter what biological state man is in at present—certainly somewhere between the two extremes of heterozygosity and homozygosity. I refer to this state, for want of a better term, as the polyzygous state, referring to the fact that man is derived from many kinds of zygotes (that is of fertilized eggs from which all of us at one time have developed). No matter where man is along the road, the continuous inbreeding of heterozygous or hybrid mice by a consistent system of restrictive mating must of necessity produce or duplicate the same biological state in which man is in at present, before the final return to another group of inbred mice has been reached. In other words, we now have polyzygous mice to go with polyzygous man. Polyzygous mice have biological or genetic variability. Do they also give rise to many kinds of tumors and cancers?

To wait for spontaneous tumors in mice takes too much time. Many of them, particularly the internal ones, do not occur until two or even three years of age. In order to fill the need, therefore, the process of the production of experimental cancer must be speeded up. For this, we make use of the cancer-producing chemical, particularly methylcholanthrene, that the chemists have synthesized. We do not intend to discuss whether the cancer-producing chemicals ever induce cancers that would not normally occur in experimental animals or merely hasten their appearance. The evidence for the final conclusion on this point is not yet available.

The past experiences of many cancer investigators have shown that when you inject methylcholanthrene subcutaneously you get a fibrosarcoma at the site of injection. The incidence of this type of tumor in my experience is not as frequent as I should expect from reading the literature and I suspect that the cancer-producing potency of methylcholanthrene is like Mark Twain's reported death, "slightly exaggerated." But one does get a large number of locally appearing fibrosarcomas at the site of injection. Every scientist in cancer research has obtained these and therefore it is not necessary to induce fibrosarcomas indefinitely. If there is any value in the concept that genetic uniformity gives cancer uniformity and genetic variability gives cancer variability, then a specific type of cancer should respond to genetic selection. This concept has been proven to be true. I proceed to eliminate fibrosarcoma not by surgery or by x-ray, but by the application of the genetic principle of the progeny test—merely in keeping the descendants for future generations of that mouse in each generation which developed fibrosarcoma last or which did not develop fibrosarcoma at the site of the methylcholanthrene injection at all—and, this is important, the elimination of all sublines that did not conform to type, that is, that did not show some resistance to fibrosarcoma. Selection without elimination would lead nowhere. This also means selection toward longevity or the increased ability to live a longer time. It was found that the C_3H mice possess great susceptibility to induced tumors. Another strain, the NH, shows a certain degree of resistance to fibrosarcoma, the mice developing them at a slower rate than do mice of the C_3H strain. Instead of getting fibroscarcomas in all mice, only approximately 90 per cent of them do so. Observations on the successive groups of NH mice indicate the positive effect of selection toward resistance or the elimination of potential cancer at the site of injection. The trend is highly significant, there being 1,000 mice in each group except toward the end when my patience could not wait for a complete complement of 1,000 mice. The next to last group contains data on 500 mice and the last one only 250.

The regime of selection produced results far beyond my placid imagination, which according to some associates is rather pronounced. Selection eliminated or prevented many fibrosarcomas from appearing, thus permitting many mice to live longer than they normally would. They either lived a normal life span without any cancer or (remember they are polyzygous mice) practically blossomed out with benign and malignant tumors all over the body. A new and vast array of very malignant tumors appeared. I not only duplicated in experimental animals many of the very malignant tumors arising in man but in certain particulars, such as the incidence of multiple malignancies, even exceeded the cancer situation of man himself.

I believe I have demonstrated* for you the production of a vast number of tumors and cancers in mice. In brief résumé, I would like to point out that now many very malignant tumors in mice are available for study. In addition to the older malignant tumors, such as epidermoid carcinoma and fibrosarcoma, that many investigators have reported, we have produced in these special polyzygous mice the following malignant tumors: (1) anaplastic carcinoma of the mammary gland which metastasizes to bone, erodes the bone and replaces the bone marrow, characteristics that are found in human cancer of the breast; (2) bronchiogenic carcinoma, metastasizing throughout the thorax, including the heart; (3) mesothelioma with extensive metastases; (4) primary carcinoma of the liver; (5) squamous carcinoma; adenoacanthoma and adenocarcinoma of the stomach with multiple metastases; (6) leiomyosarcoma of the uterus with extensive metastases throughout the belly; and (7) liposarcoma with similar widespread metastases. Susceptibility to many of these very malignant tumors is selectively handed down to subsequent generations, and one of these, adenocarcinoma of the stomach, appears in the untreated descendants for at least five generations.

The following discussion will show a new and unexpected phenomenon, the induction of germinal mutations in the experiment of injecting a powerful cancer-producing substance into mice for several successive generations. You will note that from the F_4 generation onward, both parents at sixty days of age were injected subcutaneously with 1 mg. of methylcholanthrene dissolved in 0.1 c.c. of sesame oil. All mice in direct descent developed fibrosarcomas at the site of injection. The latent period between the time of injection and the appearance of fibrosarcoma is gradually becoming longer due to selection toward resistance. All mice were brown and for several generations all their progeny were brown (brown being inherited as a recessive). The average litter size was for the first five experimental generations 5.5 and for the second five generations 4.4, or an average litter size of 5.0 mice per litter during the entire ten generations. You will note that in the third litter of mice produced by female S197062 that there appeared three unexpected black mice in addition to four normally expected brown mice. The new black pigmentation was proven to be inherited as a dominant. We therefore must conclude that we have obtained three dominant color mutations (which proved to be germinal) in the untreated descendants of mice receiving methylcholanthrene. The original mutant offspring were possibly exposed to methylcholanthrene *in utero* since their parents had been injected with this chemical before fertilization had taken place. Methylcholanthrene is known to permeate throughout the body. Several lines from these mutant black mice have been continued and tested against the appearance of induced fibroscarcomas. The brown mice of the original NHO descent had a relatively low susceptibility to induced fibrosarcomas. The three mutant blacks, however, immediately showed a tremendous increase in susceptibility to fibrosarcomas. Now all the brown descendants of these black mutant mice show the susceptibility to fibrosarcoma of the original brown stock, whereas the black descendants retain the enhanced susceptibility of the black mutants. This phenomenon of correlation between hair color and induced fibrosarcoma susceptibility to a geneticist is indicative of linkage—that is, that the gene responsible for susceptibility to fibrosarcoma induced by methylcholanthrene is carried on the same chromosome as the gene that determines whether a mouse is to have black hair or not. The suitable experiment to prove linkage and the allied genetic phenomenon of break of linkage or crossing over has been done. Complete verification of this concept has been obtained. Time alone prevents us from discussing at length these typical genetic phenomena. Many other germinal mutations involving color of hair, et cetera, have also been obtained in the descendants of mice receiving methylcholanthrene.

---

*One hundred colored photographs of benign tumors and malignant cancers had been shown.

I desire to discuss briefly, with what little time there is available, some of the biological alterations or variations that have, in addition to color mutations and alterations in susceptibility to induced tumors, been obtained in the untreated descendants of mice receiving methylcholanthrene. Mention has been made of the fact that the brown subline of the NHO strain when subjected to methylcholanthrene for several generations had on the average 4.4 mice per litter. The three black mutants referred to above immediately had an average litter of 7.7 mice; and two generations beyond their descendants had an average litter size of 11.3 mice (with a range from nine to fourteen mice per litter). This is an average litter size that is far beyond any of the mice of any strain in my laboratory, where approximately a quarter of a million mice have been studied personally during a period of more than a quarter of a century. This increased fertility has been transmitted through several generations. Other lines have developed: (1) early sexual maturity, with the vaginae opening at nineteen days compared to thirty-five days in the controls, and the first litters at forty-two days of age compared to seventy-five to ninety days in their controls; (2) extremely large first litters, average 10.3 mice compared to 5.7 mice per litter, the average for the entire mouse colony (Autopsy of a forty-two-day-old mouse has disclosed the presence of thirteen embryos approximately fourteen days of age); (3) extremely rapid growth rate with the attainment of adult body size of 80 to 83 grams in some cases as compared to 25 to 30 grams for normal mice. The effects all appear to be favorable characteristics from the biological viewpoint.

More recently, however, unfavorable biological results are beginning to appear. These are increased prenatal mortality, low fertility, such as one or two mice per litter and in some cases complete sterility and precocious senility, such as cystic ovaries at 112 days of age or at the time when normal mice in the laboratory are in the prime of life. Many embryological abnormalities such as situs inversus, dextrocardia, eye lesions, internal extravasations of blood, and imperforate vaginae have recently been obtained in the same series, but at present we cannot tell completely the causative mechanisms behind their production. We do know, however, that these biological variations have not occurred among the untreated controls.

It is the general impression, however, gained after a long thought that the initial biological effect of subjecting a mixed population of mice to methylcholanthrene over a period of many generations and many years is a stimulatory one, not only in inducing many types of tumors and cancers but also other disturbances, such as increased fertility, fecundity, body size, growth rate, etc., which may be attributes of a super race of mice. If too long continued this chemical treatment will bring about the destruction of the species, either by causing cancer to arise at phenomenally early ages or producing biological changes that are incompatible with life. But we are leaving science too far behind and becoming philosophical and my time is running out.

In résumé, therefore, permit me to say that the practical application of genetic principles has produced in mice, with the help of the organic chemist, a vast supply of many of the more malignant tumors that afflict mankind at present. If the speculative imagination of a man whose hobby it is to delve into the cryptography of the alchemists of the 15th and 16th centuries has been fruitful enough to do this as well as to open up the broader problems of biological research as applied to populations, I hope you will bear with me when I express the candid opinion based upon some results already obtained and discussed this evening, that cancer, even in the human species, will eventually be controlled—by genetic

(Continued on Page 426)

THE EFFECT OF PROSTIGMIN IN CEREBRAL PALSY

JOHN F. POHL, M.D.

Minneapolis, Minnesota

CEREBRAL palsy is the term now generally employed to designate the condition formerly known as Little's disease, the birth injured, spastic paralysis and cerebrospastic paralysis. The disorder is essentially a disturbance of the control of muscle function due to a fixed lesion of the brain occuring approximately at the time of birth.

The deficit in the nervous system is permanent and irreparable, hence little hope can be entertained for a cure of the disorder. On the other hand the child is a growing and developing organism potentially capable of instituting new and more complex patterns of activity. This factor is active in the child with cerebral palsy as well as the normal child. Exploitation of this natural tendency for motor development should lead to more efficient control of the muscles. Treatment has mainly been directed along the line of imitating the normal motor patterns, hoping to encourage intact parts of the brain to take over the function of the damaged parts and install new motor pathways. This type of treatment usually is a long slow process and frequently seems of little benefit.

Drugs have been found of little value for permanent relief. It is possible to reduce the spasticity and other abnormal motor activity but this does not automatically improve the child's control over the muscles. The drugs have been of two types, those acting centrally to depress the nervous system, such as the barbiturates, and those acting peripherally to block the flow of impulses at the myoneural junction such as curare. Withdrawal of such drugs has been invariably followed by return of the muscular disorder in its previous form and severity.

According to two recent reports[1,2] the drug, prostigmin, has seemed to be much more promising and worthy of consideration than have those used in the past. Schaubel[2] treated ten severe cases of spastic cerebral palsy with tetraplegic involvement over a period of eight months. Previous to beginning medication none of these patients had understandable speech and none were able to feed themselves but they accomplished these functions during the period of prostigmin medication. All had serious disability in walking but at the end of the test period six patients were walking independently and the other four needed only crutches to walk. Schaubel considered prostigmin a valuable adjunct to the training program in spastic cerebral palsy. Kabat[2] reported five cases of the spastic type of cerebral palsy to be definitely improved by prostigmin medication. Only two of the cases were reported in detail. In one of these it was mentioned that the improvement was retained after prostigmin was discontinued.

Cerebral palsy is a crippling condition of considerable importance. The Children's Bureau of the Federal Government, under which functions the program for the care of crippled children in the various states, lists cerebral palsy as second only to infantile paralysis as a cause of crippling in children. Of 289,342 children under the age of twenty-one on the registry for all causes in 1940, cerebral palsy accounted for 10.2 per cent while infantile paralysis was the cause of registration for 18.9 per cent. At the Michael Dowling School for Crippled Children in Minneapolis approximately 60 per cent of the students at the present time are afflicted with cerebral palsy. About eighty-five patients with the condition attend constantly and are under care. This includes only those who are so severely affected as to be physically unable to attend regular schools. Improvement is slow with the ordinary physical methods even in the hands of the group of highly trained personnel with which the school is staffed. Those who work with cerebral palsy are well aware of the desirability of help from any source.

The disorder of cerebral palsy has several manifestations depending upon the part of the brain harboring the lesion. The majority of the cases fall into two main groups, the spastic marked by specific muscle hypertonicity and the athetoid characterized by uncontrollable agitated movements without pattern. The spastic cases make

Part of the drugs used in the study were supplied by Hoffmann-La Roche, Inc., and grateful acknowledgment is hereby given.

up the larger percentage, but the athetoid group also constitutes a fair number of the total. A small number, probably not more than 2 or 3 per cent, consist of the ataxic, mixed and rigid types of the disorder. Many of the athetoid group have a tenseness of muscle which is considered to be an attempt to control the athetoid motions and this variation is called the tension athetoid. Many of this tension group are difficult to distinguish from the true spastic type. The tension has been considered a voluntary effort on the part of the patient to control the athetosis but undoubtedly in many instances the tension is entirely subconscious. The published reports on prostigmin[1,2] were on the spastic type of cerebral palsy.

In view of the encouraging results which have been reported on the use of prostigmin it was decided to subject a group of ten children at the Michael Dowling School for Crippled Children to a test period preliminary to administration of the drug to the entire group of children with cerebral palsy. Five typical cases of the spastic type were selected on the basis of age range, being six, nine, ten, fourteen and eighteen years old, respectively. Details of these cases are given in the accompanying reports. The other five cases selected for trial were of the tension athetoid type, being seven, eight, nine, sixteen, and seventeen years old, respectively. It was felt that the athetoid group would serve as a control to some degree since relief of the tension should allow the athetosis to become more manifest, although no information was available as to the effect of prostigmin upon the athetosis element itself. It will be noted in the table that most of the children had been under treatment at the school for a number of years. The condition of each child was well known and the rate of improvement under ordinary physical methods had become definitely established.

The abilities of each of the ten children were carefully noted at the beginning of the test period and recorded on a special achievement scale chart. This chart listed activities beginning with the simple ability to turn over or sit up and progressed through increasingly complex activities such as skipping or hopping and catching or throwing a ball. Specimens of handwriting were collected. Voice recordings were made to study rate and volume of speech as well as clarity. Moving picture records were made of selected activities common to the age group under observation such as standing, walking, eating, dressing, and piling blocks. The type of data outlined above was collected at regular intervals for study of progress. Upon completion of the test period of six months, additional information was sought through a questionnaire addressed to various persons who had had contact with the child, such as the parent, school teacher, bus driver, and room attendant as well as those directly in charge of treating the patient such as the physiotherapist, speech clinician, and the occupational therapist. Where the child was old enough to be reliable an opinion was sought directly from the child as to the effect of the drug.

The daily program of care and treatment of the children was not changed in any way except for the administration of the drug. The dosage of prostigmin administered was that used by Schaubel[2], given by the oral route as follows:

Children under age 8—Prostigmin bromide 15 mgs. once daily; atropine sulfate 1/600 gr. once daily.
Children age 8 to 12—Prostigmin bromide 15 mgs. twice daily; atropine sulfate 1/300 gr. once daily.
Children over age 12—Prostigmin bromide 15 mgs. three times daily; atropine sulfate 1/200 gr. once daily.

Prostigmin is a synthetic drug whose physiological action is similar to that of the natural alkaloid physostigmine, in that its principal effect upon the body is as if the parasympathetic nervous system were being stimulated. A further action which concerns the present study is that prostigmin depresses muscle tone and reflexes and apparently inhibits the discharge of stimuli from the anterior horn cells of the spinal cord. This is the basis of its application to the treatment of spastic paralysis. An advantage over physostigmine is in the relative absence of undesirable side effects such as nausea, salivation, sweating, dyspnea, and epigastric pain. These untoward effects where they occur can be abolished by atropine without destroying the desirable action of the prostigmin, hence atropine was given in the cases under consideration in order to avoid possible undesirable symptoms from the prostigmin.

The prostigmin was well tolerated in all ten of the patients under observation. At the end of three months it was evident that there was no significant improvement in any of the cases and the dosage of prostigmin was increased by 50 per cent. One athetoid patient (No. 8) after three months of oral administration was placed on prostigmin methylsulfate by subcutaneous injection as used by Kabat[1] in his report on spastic cases.

At the end of six months a final examination and record was made of all patients, and the medication was discontinued. It was the opinion of all observers that there was no measurable objective evidence of improvement which could be attributed to prostigmin in any of the patients. One of the spastic patients and two of the athetoid group stated that they felt more relaxed while taking the drug. Two of the parents of the other spastic cases thought there was questionable improvement and one of the parents of the other athetoid cases thought the child was more relaxed. None of the patients or the parents requested continuation of the prostigmin beyond the six months experimental period although the drug was made available to all for further administration.

Summary

A group of ten children with typical cerebral palsy, eight of whom had been under physical treatment for several years, were given oral prostigmin bromide and atropine sulfate in recommended doses over a period of six months. The cases were divided between the spastic type and the tension athetoid type. No measurable objective evidence could be obtained that the medication improved the control of muscle function. Four of the patients had never learned to walk and they did not accomplish walking during the period of medication. Two additional patients who walked with crutches were not able to discard the crutches during the period of medication. Subjectively three patients reported that they felt slightly more relaxed while taking the drug and the parents of three additional patients stated that the child appeared slightly more relaxed. This effect was noted in both the athetoid and the spastic group. None requested continuation of prostigmin beyond the six months' period of observation. We have not given prostigmin to any of the other patients with cerebral palsy at the Michael Dowling School for Crippled Children.

Spastic Type

Case 1.—L. S., male, aged six. Diagnosis: Tetraplegia, moderate severity. Attendance at Dowling School prior to the outset of the test: eighteen months.

At the time of starting the prostigmin test the patient had learned to stand alone for thirty seconds and could take two steps unassisted. He was able to dress and feed himself. His speech was barely understandable.

At the end of the six months' test period, he was able to stand alone for two minutes and he would walk unaided for twenty-two steps. The speech clinician reported a slight improvement in the clarity of his speech and a reduction in the effort required to speak.

Opinion.—The child appears to have improved. However, the child was improving at the time of starting the test. His mother stated, "L. has been improving steadily ever since going to Dowling School. It is hard to say whether the drug had such a big effect or whether he is just improving from treatment." The consensus of all observers was that the rate of improvement was not accelerated by prostigmin.

Case 2.—A. G., female, aged nine. Diagnosis: Right hemiplegia, moderate severity. Attendance at Dowling School prior to the outset of the test: five years.

At the beginning of the test period the patient had very limited use of the right hand. She could assist in dressing herself but she was unable to grasp an object with her right hand. She was not able to feed herself with her right hand. Her walking was slightly affected. Her speech was normal.

At the end of the test period her condition was unimproved. The patient stated that she "felt more relaxed."

Opinion.—There was no objective evidence of improvement under prostigmin therapy.

Case 3.—B. A., female, aged ten. Diagnosis: Tetraplegia, severe involvement. Attendance at Dowling School prior to the outset of the test: six years.

At the beginning of the test period she was able to grasp with her hands but had only gross motions. She was able to feed herself and to partially dress herself. Her balance was poor. She could stand and walk only with the aid of crutches. Her speech was slightly affected.

At the end of the test period her condition was unimproved. Her parent stated that she seemed more relaxed.

Opinion.—There was no objective evidence of improvement under prostigmin therapy.

Case 4.—K. R., male, aged fourteen. Diagnosis: Right hemiplegia, moderate severity. Attendance at Dowling School prior to the outset of the test: nine years.

At the beginning of the test period the patient was able to grasp and pick up objects with his right hand but made little practical use of his hand. He was able to walk actively but tended to walk on his toes. His speech was affected by a stutter.

At the end of the test period his condition was unimproved. The patient stated that "the drug was of no benefit."

Opinion.—There was no improvement under the prostigmin therapy.

Case 5.—M. T., female, aged eighteen. Diagnosis: Tetraplegia, severe involvement. Attendance at Dowling School prior to the outset of the test: eight years.

At the beginning of the test period the patient had learned to walk with crutches a distance of 50 feet but could not stand unassisted. She was able to feed and dress herself. She was able to write and her speech was clear.

At the end of the test period her condition was unchanged. The patient stated that she felt more relaxed. The drug was "not of much benefit, however," according to her statement.

Opinion.—There was no improvement under the prostigmin therapy.

Athetoid Type, With Tension

Case 6.—M. N., female, aged seven. Diagnosis: Tension athetoid, general involvement, severe. Attendance at Dowling School prior to the outset of the test: two years.

At the beginning of the test period she was barely able to feed herself and could grasp objects only with difficulty. She was able to stand or balance only momentarily. She would attempt a step or two. She held her legs rigidly to aid herself in balancing. Her speech was fairly clear. She was not able to write.

At the end of the test period the child was able occasionally to grasp and hold a glass of water but she could not drink the water without accident. Her condition otherwise was unchanged. The parents stated that "it seems that M. is much more relaxed. She is not as restless when she sleeps."

Opinion.—There was very slight objective evidence of improvement under the prostigmin therapy.

Case 7.—D. B., male, aged eight. Diagnosis: Tension athetoid, general involvement, moderate severity, the right arm was particularly affected. Attendance at Dowling School prior to the outset of the test: three months.

At the beginning of the test period the child was quite capable. He was able to dress and feed himself. His right arm was quite tense but the patient was left handed. His gait was unsteady. His speech was unaffected. There were intermittent uncontrolled motions of his head and neck.

At the end of the test period there was no noticeable improvement. His head had fallen backward and the child had to hold his head up with his hand. The parents stated, "for a short time we noticed a distinct improvement but on the whole there has been no noticeable improvement at all."

Opinion.—There was no improvement under the prostigmin therapy.

Case 8.—K. M., female, aged nine. Diagnosis: Tension athetoid, general involvement, moderately severe. Attendance at Dowling School prior to the outset of the test: five years.

At the beginning of the test period the patient was able to partially grasp objects and to feed herself. Swallowing was difficult and her balance was very poor. She could stand alone only momentarily. She was quite tense and rigid on standing. She could walk short distances pushing a chair. Her speech was barely understandable. Her printing was legible. The athetoid movements were most noticeable on intention. She was able to dress herself.

At the end of three months of oral prostigmin therapy there was no improvement. The medication during this period from April to July 1945 was 15 mgs. of prostigmin (orally twice daily) plus 1/300 gr. of atropine once daily.

At the end of the three months' period, she was placed on prostigmin methylsulfate, subcutaneously as follows:

July—1 c.c. 1:4000 prostigmin methylsulfate plus 1/300 gr. of atropine—once daily.

August—1.5 c.c. 1:4000 prostigmin methylsulfate plus 1/300 gr. of atropine—once daily.

September—1 c.c. 1:2000 prostigmin methylsulfate plus 1/500 gr. of atropine—twice daily.

(At this time she became overdosed. She began to be listless, tired, drooled, lost interest, and would not attempt her school work. Her speech was difficult and she walked less.)

September 15, 1945—1 c.c. of 1:2000 prostigmin methylsulfate plus 1/300 gr. of atropine—once daily.

At the end of the six months' test period there was no improvement under the prostigmin therapy.

Opinion.—There was no improvement under the prostigmin therapy.

Case 9.—P. M., male, aged sixteen. Diagnosis: Tension athetoid, general involvement, severe. Attendance at Dowling School prior to the outset of the test: seven years.

At the beginning of the test period he was able to partially feed himself but he could not drink liquids. He was barely able to grasp objects. He could not dress himself. He was able to walk 25 feet but had severe tenseness. He had writhing movements at times in an attempt to control his limbs. His speech was fairly good. His writing was illegible. He was able to use the typewriter.

At the end of the test period his condition was unchanged. The patient stated that he felt "slightly more relaxed."

Opinion.—There was no objective evidence of improvement under the prostigmin therapy.

Case 10.—E. P., female, aged seventeen. Diagnosis: Tension athetoid, general involvement, severe. Attendance at Dowling School prior to the outset of the test: eleven years.

At the beginning of the test period the patient was unable to dress herself, feed herself, or care for her toilet. Severe tenseness prevailed over her entire body with occasional severe writhing movements. She was not able to stand but attempted to walk when supported under her arms. Her speech was involved but it was understandable. She was not able to write.

At the end of the test period her condition was unimproved. The patient stated that she felt less tense and had better control of her hands. The parents did not notice any improvement.

Opinion.—There was no objective evidence of improvement under prostigmin therapy.

MALARIA

LT. COL. D. E. NOLAN, MC, MAJOR H. WARSHAWSKY, MC, and
CAPTAIN G. W. PEDIGO, JR., MC
Dayton, Ohio

PRIOR to World War II, malaria in many sections of the United States was of infrequent occurrence. From 1930 to 1944 an average of three cases of malaria per year were admitted to this hospital, exclusive of therapeutic malaria. During 1945 there were 154 separate cases of malaria admitted. This increase was due entirely to the return of veterans from malarial regions. Many did not know they were harboring the malarial parasite at the time of their discharge as they had received prophylactic doses of atabrine while in service and only after this drug was discontinued did the disease become manifest.

The purpose of this paper is to present a few examples of how malaria may complicate other diseases, and, conversely, how other diseases may complicate malaria, in the hope that other physicians, who have not been as fortunate as we in seeing a fairly large number of malarial patients, may be benefited.

Other Diseases Complicated by Malaria

Case 1.—R. C. D., a white man, aged thirty-five, was admitted to this hospital October 18, 1945, for the treatment of malaria. The history revealed service in the Southwest Pacific during which he had malaria and amebic dysentery. He recovered and was subsequently discharged because of accumulated points. Ten days prior to admission he developed diarrhea and pains in the left upper quadrant of the abdomen, accompanied by irregular chills, fever and sweats. He was acutely ill on admission with a temperature of 102 degrees. The only significant physical finding was marked tenderness and muscle spasm in the left upper abdominal quadrant. No definite splenomegaly could be ascertained. A blood smear for malarial parasites was negative at this time. The white blood count was 13,000 with 81 per cent polymorphonuclear cells. The red blood count was 4,000,000 with hemoglobin 86 per cent. Blood cultures, urinalyses and liver function studies were accomplished with negative results. Repeated studies of the stool for amebae were negative. His febrile and toxic course did not abate. None of the laboratory studies revealed any significant abnormalities except for the gradual development of a hypochromic, microcytic anemia. A small mass became palpable in the epigastrium which was thought to be contiguous with the liver. A diagnosis of amebic abscess of the liver was made and emetine hydrochloride therapy by the parenteral route was started. On November 21, 1945, an exploratory laparotomy was done which disclosed an abscess located on the anterior surface of the left lobe of the liver. This was drained and packed. The characteristics of the pus were typical of an amebic abscess but no organisms were recovered. Neither were amebic cysts found in a biopsy specimen removed from the wall of the abscess. Daily irrigations of the abscess cavity with 1:1000 emetine hydrochloride were administered and the patient's course was very gratifying. On November 25, 1945, he suffered a chill with a temperature of 103.4. A blood smear revealed plasmodium vivax. Response to atabrine therapy was prompt. The patient made an uneventful recovery.

Case 2.—U. W. P., a colored man, aged twenty-five, was a veteran of the Northern Burma campaign. He was discharged because of accumulated points, September 1, 1945. On the day of his discharge he suddenly developed severe upper abdominal cramping pains with associated nausea. He had two bowel movements but the stool appeared normal. There was an increase in his symptoms for the next five days and he was admitted to this hospital, September 7, 1945. There was no past history of gastro-intestinal disturbance and his past history had been negative for any serious illness. On admission the patient was acutely ill. He was in severe pain, rolling and tossing in bed. He lay with his knees flexed on his abdomen. He was perspiring freely. The temperature was 99.2, the pulse was 100, and the respirations were 20. There was marked rigidity of the abdominal muscles in the upper half of the abdomen with marked tenderness. There was also fullness across the upper abdomen. The lower abdomen was soft. No jaundice was noted. Rectal examination was negative. The white blood count was 20,950 with 80 per cent polymorphonuclear cells, 15 per cent lymphocytes and 5 per cent monocytes. A smear for malaria was negative at this time. A scout film of the abdomen was negative. The urinalysis was negative. It was thought by the Surgical Service that an exploratory laparotomy should be done because of the possibility of a perforating duodenal ulcer. At the operation the only finding was an enlarged liver and spleen. The liver was firm and there were nodulations over the surface. A biopsy was taken. The postoperative course was uneventful until September 22, 1945, when the patient developed diarrhea. Stool examination showed Endamoeba histolytica and the biopsy of the liver showed amebic hepatitis. He was placed on emetine and later carbarsone with excellent clinical response. On October 14, during his convalescence, he suddenly had chills and fever and a blood smear was found to be positive for plasmodium vivax. Therapy

---

From the Medical Service, Veterans Hospital, Dayton, Ohio. Published with the permission of the Acting Surgeon General of the Veterans Administration who assumes no responsibility for the opinions expressed or conclusions drawn by the authors.

with atabrine gave prompt results. He was discharged November 5, 1945.

Case 3.—H. E., a white man, aged twenty-five, was a veteran of the South Pacific area, and was on atabrine as prophylaxis against malaria during his overseas tour. While overseas he had diarrhea with blood, mucus and purulent material in his stools and Endamoeba histolytica was found on stool examinations. He apparently completely recovered and in November, 1945, was discharged because of accumulated points. One week prior to his admission to this hospital he had recurrent diarrhea with blood, mucus and pus noticed in his stools. He also complained of weakness and had a low grade fever. Examination of the stools showed Endamoeba histolytica, and sigmoidoscopic examination showed ulcers typical of amebic dysentery in the colon. He was placed on diiodoquin therapy and was convalescing satisfactorily with marked regression of symptoms for three days when he suddenly began to chill, elevation of temperature was noted, and profuse perspiring was present. Smears taken immediately were positive for plasmodium vivax malaria. He was placed on atabrine in addition to the diiodoquin and his response and course were uneventful thereafter.

Comment.—These three cases illustrate the frequent association of amebic dysentery with malaria. In addition these patients during their convalescence from amebic dysentery developed chills and fever as a complication. In such cases, unless doctors are malaria-conscious, such incidents will cause considerable alarm. This may result in many expensive diagnostic examinations in an attempt to discover the etiology of the complicating chills and fever, when a simple blood smear would immediately establish the etiology.

Case 4.—C. J. D. a white man, aged twenty-eight, was a veteran of the South Pacific. He was admitted March 4, 1945, with a history of epigastric pain occurring one and one-half hours after meals which was relieved by food and amphojel. Nausea, vomiting, tarry stools and weakness had been noted for three months. Study revealed a duodenal ulcer, and proglottids of Taenia saginata were found in the stool specimens. On ulcer regimen he continued to feel weak and listless. A few days later he developed chills and fever. Since we were aware of the frequency of malaria complicating other diseases, blood smears were examined. They were positive for plasmodium vivax. Appropriate therapy with atabrine, in addition to ulcer regimen, resulted in complete recovery.

Comment.—This case is an example of malaria developing as a complication in a patient under therapy for active duodenal ulcer. The chills and fever developed suddenly and unexpectedly. It is of further interest that three distinct disease entities coexisted.

Case 5.—C. E. W., a white man, aged twenty-one, was a veteran of the North Africa and Italian campagain. His past history was essentially negative. He was on atabrine as prophylaxis against malaria while on duty overseas. He became acutely ill about three days prior to admission to this hospital with a history of sore throat, headache, vomiting, leathargy and fever. On physical examination he appeared acutely ill. His temperature was elevated. His throat was inflamed. His neck was stiff and the Kernig test was positive. A spinal tap was done and grossly purulent spinal fluid was obtained. The patient was treated with sulfadiazine and penicillin and had a satisfactory convalescence. The etiological organism of the meningitis unfortunately could not be demonstrated by the laboratory. During his satisfactory convalescence, approximately twenty-one days after admission, the patient suddenly had chills followed by a fever of 102.4. A relapse of his meningitis or some complication of his meningitis was immediately suggested, but the medical staff was alert to the possibility of malaria suddenly appearing in a young veteran who had served in a malaria-infected region of the world during the war and a blood smear was made which proved to be positive for plasmodium vivax. On atabrine therapy his future course was uneventful.

Case 6.—A. C. McN., a white man, aged thirty-four, was admitted, January 4, 1946, for treatment of pneumonitis. He had been ill at home for about one week prior to admission with fever, pain in the right chest, and a cough. He was seen by his private physician and placed on one of the sulfonamides. There had apparently been marked improvement with the sulfa therapy although the pain in the right chest persisted. He was afebrile on admission to this hospital. A chest x-ray showed changes indicative of an inflammatory process involving the right lower and right upper lung fields. The physical signs indicated consolidation in the right lower lobe area posteriorly. The veteran's convalescence was uneventful with gradual clearing of the physical signs and improvement in well-being. However, on January 23 a chill developed and temperature rose to 104 degrees. Blood smear taken promptly revealed plasmodium vivax. Atabrine therapy was instituted at once and a satisfactory clinical response was effected.

Case 7.—L. J. W., a white man, aged twenty-three, was admitted December 7, 1945. He had been stationed in the Southwest Pacific area for twenty-eight months. Since March, 1945, he had five attacks of malaria, each one responding promptly to quinine or atabrine therapy. However, weakness persisted during the intervals between relapses and progressive loss of weight occurred. At the same time diarrhea consisting of five or six loose, bulky, foul and frothy stools daily made its appearance. He had lost fifty-five pounds since March, 1945, and had developed burning and soreness of his mouth and tongue. Abdominal cramps had not been noted at any time. On admission the veteran was very weak, poorly nourished and poorly developed; temperature 98, pulse 120, respirations 20. Signficant findings included pallor, emaciation, smooth red tongue, tenderness in left upper abdominal quadrant and slight enlargement of the spleen. Within a few hours after admission he suffered a chill with temperature rise to 102.4 degrees. Plasmodium vivax was demonstrated in the blood and the routine course of atabrine was instituted. No subsequent febrile episodes occurred. The red blood count on admission was 1,410,000 with 31.3 per cent hemoglobin. The white blood count was 2,030 with a normal differential. The glucose tolerance test revealed a flat curve. Stool studies were not significant except for the negative finding of fat with sudan III stain. Gastric analysis revealed absence of free hydrochloric acid in the fasting specimen with maximum free acidity of twenty-six units 45 minutes following histamine stimulation. Blood chemistry was normal including a blood calcium of 11 mgms. and a blood sugar of 101 mgms. Gastro-intestinal series revealed no abnormality. A diagnosis of sprue was established and treatment with an initial whole blood transfusion, liver extract, vitamin B complex, high carbohydrate and low fat diet was instituted. The bulky diarrhea ceased, rapid improvement in the blood picture took place, and remarkable weight gain and recovery of well-being occurred. He had gained thirty-three pounds at the time of his discharge on January 19, 1946. The blood count on this date was 4,210,000 RBC with 85 per cent hemoglobin and 11,000 WBC with a normal differential count.

Comment.—This case illustrates that the response to atabrine therapy when administered promptly, in the treatment of a relapse of malaria, should be complete if the malaria is uncomplicated. Not only should the fever, chills and malaria subside promptly, but also the weakness and lassitude that go with the acute relapse. With persistence of symptoms of any kind between well treated relapses, it is imperative to search carefully for some other disease entity. In this case the severe anemia, if not studied carefully, could easily have been interpreted as being caused by the malaria. However, the history of bulky, foul diarrhea supported by the laboratory findings established the diagnosis of the sprue syndrome which explained the persistence of chronic ill health between the relapses of malaria.

Case 8.—F. S., a white man, aged thirty-seven, a veteran of the South Pacific, received atabrine as prophylaxis against malaria while in this section. He was discharged from service because of accumulated points and five days later developed chills, fever, and cough with expectoration of mucopurulent material. He was admitted to this hospital on November 3, 1945. On admission pneumonia was suspected but an x-ray of the chest was negative. The urine was negative. The red blood count was normal. The white blood count was 10,000 with 79 polymorphonuclear cells, 20 lymphocytes, and 1 eosinophile. A smear for malaria was positive for plasmodium vivax. He was placed on atabrine and his temperature returned to normal and for two or three days he appeared much improved. At this time a low grade fever appeared and he developed pain in the lower right chest on deep breathing with weakness and generalized aching. A repeat x-ray of the chest showed increased density in the right lower lung field consistent with pneumonia. He was placed on penicillin and his recovery was uneventful, with the chest lesion slowly clearing.

Case 9.—H. W., a white man, aged twenty-seven, was a veteran of the Italian campaign. He was admitted to the hospital with a history of chills and fever of two weeks' duration. In addition he complained of abdominal cramping pain with occasional vomiting attacks since the onset of his illness. No blood was ever noted in his vomitus, and no black tarry stools had been noted. The abdominal distress was usually relieved somewhat by alkalis and was most noted when his stomach was empty. On admission the red blood count was 2,100,000 with 46 per cent hemoglobin. A smear was positive for plasmodium vivax. He was placed on atabrine and his fever rapidly subsided. His anemia improved on iron and adequate food intake but he continued to have abdominal distress. A gastro-intestinal x-ray study was done and evidence of a duodenal ulcer was found. Ulcer regimen was instituted and the symptoms related to his malaria and ulcer responded satisfactorily.

Malaria Mistaken for Other Diseases

Case 10.—D. L., a white man, aged thirty-two, a South Pacific veteran, was admitted to this hospital with a history of chills and fever, a cough, a pain in the left chest, and a sore throat. On admission his temperature was 104.2. He appeared acutely ill and toxic. He coughed frequently. The throat was red and injected. He was thought to have acute tonsillitis and possible pneumonia. He was placed on sulfonamide therapy for these provisional diagnoses. An x-ray of the chest was negative and no clinical response was noted with the sulfonamides. Blood smears were taken and plasmodium vivax was found. The sulfonamides were discontinued and treatment with atabrine resulted in prompt recovery.

Comment.—This case illustrates how frequently patients are placed on either sulfa or penicillin without a careful study as to the etiology of the fever and other related complaints. It also illustrates how malarial infection may be masked in its presentation of symptoms and findings.

Case 11.—G. W. B., aged twenty-nine, a white veteran of South Pacific, received atabrine as prophylaxis against malaria while serving overseas. He developed abdominal pain with cramps and vomiting while in the tropics and was returned to the States. After diagnostic studies were made he was separated from service with a diagnosis of gastritis. He continued to have the above complaints plus chills and fever, and was admitted to this hospital on September 16, 1945. The red blood cell count was 2,921,000 with the hemoglobin 66 per cent, and the white blood count was 6,250. The urinalysis was negative. A smear for malaria was positive for plasmodium vivax. He was placed on atabrine therapy with complete relief from his symptoms resulting. He was discharged free of symptoms on September 26, 1945.

Comment.—This is an interesting case showing the atypical course that malaria may take. This patient was thought to have chronic gastritis. His symptoms were not those usually seen in malaria. However, a smear for malaria was positive and all symptoms completely disappeared on treatment with atabrine.

Case 12.—L. P. B., a white man, aged twenty-six, was a veteran of the South Pacific. He was discharged from the Army, June 10, 1945. On July 2, 1945, he developed a sore throat, chills and fever. The family physician was consulted and the patient was treated for "Strep throat" with sulfa tablets. He did not improve, and he became weaker and continued to have chills every other day. He was admitted on August 2, 1945, to this hospital. The red blood count at this time was 1,430,000 with 30 per cent hemoglobin, and the white blood count was 3,350 with 57 per cent polymorphonuclear cells, 40 lymphocyte, and 3 monocyte. Marked anisocytosis was noted on the blood smear. He was transfused and given iron and atabrine with other general supportive care. His recovery was complete and uneventful.

Comment.—This illustrates how a patient may be carried for weeks with an erroneous diagnosis. Not until a severe anemia occurred and the patient became very weak and quite ill was a smear for malaria made. Considering the entire course of his illness and the time required for him to regain his health, many weeks of work were lost by this patient which could have been avoided if malaria had been considered earlier.

Conclusions

1. When a physician encounters a veteran with chills and fever who has had service in a malarial region, he should consider the possibility of malaria, amebiasis and other tropical diseases.

2. In cases of trauma, surgery or other illness in veterans of World War II when the clinical course is complicated by chills and fever, malaria should always be excluded. From our experience we find this is not infrequent and presents a problem to all sections of the country. Many expensive and time-consuming laboratory studies may be avoided in such instances if physicians are malaria-conscious.

3. When the course of malaria is complicated by diarrhea, amebiasis should be excluded since amebic dysentery and malaria are frequently found coexisting in the same patient.

4. Atabrine and quinine do not cure vivax malaria and recurrent attacks are common and frequently bizarre. The interval between recurrent attacks may be only a few days.

5. Blood smears are easily done and should properly precede therapy with atabrine or quinine.

6. The coexistence of malaria with other diseases constitutes a challenge to the diagnostic acumen of the medical profession and presents a very interesting problem.

MEN, MICE, MALIGNANCY

(Continued from Page 418)

principles. I do not mean by some utopic eugenic practice, but by the discovery of the mechanism within the animal body which produces resistance to cancer in all its phases. When this is ascertained and completely understood, we are justified in hoping that this principle will control human cancer.

In closing, I would like to leave you with two quotations. One is by Walt Whitman: "And a mouse is miracle enough to stagger sextillions of infidels." Robert Burns probably did not have cancer in mind, but he may very well have had when he said, "The best laid schemes o' mice and men, gang aft a-gley."

MALARIA IN MINNESOTA

THOMAS B. MAGATH, M.D., F.A.C.P.
Rochester, Minnesota

ONE who reads the early medical literature of Minnesota will see frequent reference to 'malaria" and "typhoid-malaria." While he will be unable to differentiate those cases which were ndigenous to the state from those in which the patient arrived by way of the river traffic, the belief is generally held that there were many "native" cases. With the lessening of the importance of the Mississippi River as a means of passenger transportation and with the clearing of lands and draining of swamps, and perhaps as a result of unknown factors, malaria has almost disappeared from the state, although in some years, from one to five persons have contracted the disease in Minnesota.

Following World War I there was no appreciable rise in reported cases. However, in 1919 n the vicinity of Red Wing and Bay City there were eleven clam fishermen who contracted the disease. With renewed activity on the river in the middle thirties, malaria again visited Minnesota and its sister state Wisconsin. From 1935 to 1937, nclusive, there were twenty-two cases reported, of which eleven were indigenous. In 1938 there were eight, of which three were indigenous, and in 1939 there were twenty-three cases, of which twenty-one were indigenous. The number of cases n Wisconsin was comparable and reached a high in 1939 with twenty-eight cases. Most of these cases were found along the river from Wabasha, Minnesota, to LaCrosse, Wisconsin. In 1940, thirteen cases, with four indigenous ones, were reported, and in 1941, nine cases were recorded.

A survey, during these years, conducted under the auspices of the U. S. Public Health Service and the State Boards of Health of Minnesota and Wisconsin, revealed the interesting fact that owing to flooding of land near the river and the retention of these swamps throughout the summer and early fall and owing to cutting of trees which let in sunlight, an enormous breeding area for Anopheles had developed. Of the larvae captured, 57.4 per cent were Anopheles quadrimaculatus, the chief transmitter of malaria in the United States. Catching adult mosquitoes in this area disclosed that Anopheles quadrimaculatus was the predominant mosquito.

As the victims were diagnosed and treated, as the severe winters took their toll of infected mosquitoes and as the workers on the dams returned to their Southern homes, removing most of the reservoirs of infection, malaria again receded in the state. Now, with the returning service and other overseas personnel, malaria and Minnesota again become an important combination.

During the present war years the following number of cases have been reported: 1942, one, which was indigenous; 1943, seven cases; 1944, sixty cases, and 1945, three hundred and sixty-six cases. None of these in the last three years has been indigenous; however, one person contracted the disease as a result of a transfusion from an ex-serviceman. Since 1912 there have been fourteen deaths reported as being caused by malaria, and fifty-six indigenous cases.

No one will ever know just how many military and other personnel connected with the war effort contracted malaria. Not all cases occurred among overseas personnel, for many cases occurred in our southern camps. From very incomplete data one may expect something on the order of 1,000 cases to occur in Minnesota over a peak period of two or three years. Many of these persons will have their first attack in the state, because the suppressive treatment with atabrine was highly effective. Others will be noted when having one of their relapses, so common in cases of tertian and quartan malaria. Fortunately, few cases of estivo-autumnal malaria (falciparum malaria) will be encountered, for the long suppressive regimen will have cured almost all of these infections.

Physicians should remember that thousands of persons other than military personnel were overseas for long periods and when symptoms suggestive of malaria appear in any of these, examination of the blood should follow promptly. Rarely is treatment justified before a diagnosis has been established; diagnosis is best accomplished by examining thick smears and indeed this method is imperative. This is a specific technical procedure and frequently is the only means of making

---

Dr. Magath is Chief of the Division of Clinical Pathology, Mayo Clinic, Rochester, Minnesota.

a positive diagnosis. Once the diagnosis has been established, treatment should be begun at once.

Many drugs have been tested. While a new and better one may be forthcoming, at present atabrine (quinacrine hydrochloride) is the drug of choice. A new drug, SN7618(7-chloro-4-[4-diethylamino-1 methylbutylamino] quinoline) and other compounds have been announced as being superior to atabrine, but it will be some time before they are generally available and accepted. Plasmochin does not offer any advantage in treatment and should not be used, as a rule.

In uncomplicated cases, two tablets of atabrine (0.2 gm. or 3 grains) should be given orally every six hours night and day for five doses (total 1.0 gm.), followed by one tablet (0.1 gm. or 1½ grains) three times a day after meals for six days (total 2.8 gm. of atabrine in seven days).

In cases in which there is severe vomiting or when the patient is unable to retain orally administered medicine, two ampules of atabrine (0.2 gm. each) in 5 c.c. of sterile water may be given intramuscularly, one in each buttock. If necessary, one or two additional doses of 0.2 gm. (one ampule) may be given at intervals of six to eight hours. Oral medication should then be resumed as soon as possible, the total dosage for the first forty-eight hours being 1.3 gm. Thereafter one tablet (0.1 gm.) should be given three times daily for five days (total dosage 2.8 gm.).

In a few instances, the dose of atabrine by mouth may not be tolerated. In these cases, quinine should be used. Likewise in a case in which there are unusually severe symptoms, quinine may control the attack more rapidly than atabrine. If the patient can retain quinine that has been administered orally, give 10 grains (0.65 gm.) of quinine sulfate three times a day for four days and 10 grains (0.65 gm.) daily for six more days. If orally administered medicine cannot be retained, give quinine intravenously (10 grains or 0.65 gm. of the dihydrochloride in 300 to 1,000 c.c. of isotonic saline solution). This may be repeated in six to eight hours. There is no advantage in parenteral administration of either atabrine or quinine if the patient can retain the drug when it is given orally.

If quinine is first used intravenously because of the severity of the attack and not because of intolerance to atabrine, the latter is given intramuscularly at the same time (0.2 gm.) and the usual course of 2.8 gm. of atabrine is completed as previously described.

Cerebral malaria may occur as the first attack of Plasmodium falciparum (malignant tertian) malaria. This type of malaria will be encountered very infrequently. In such cases 10 grains (0.65 gm.) of quinine dihydrochloride in 300 to 1,000 c.c. of isotonic saline solution should be given intravenously at once and repeated for one or two doses at intervals of six to eight hours. Oral administration of atabrine or quinine is started at the same time or as soon as the patient can ingest any medicine.

Although the hazard of inoculating a patient with malaria during the act of blood transfusion has increased greatly since the return of so many persons who have been in malarious areas, the possibility of a disastrous effect on the patient is not great so long as physicians are alert to the possibility. Persons acquiring malaria by this means respond readily to moderate treatment and as a rule do not have a relapse.

In spite of these remarks, there is no justification for chancing an inoculation of malaria by not taking suitable precautions.

It is possible to use malarious blood for transfusion of patients if the blood can be held for about ten days before using. This time will allow for the death of the parasites. However, if this is not possible, the following general rules may serve as a guide:

Rule 1. If the prospective donor has been in a malarious area and has had an attack of malaria, he should not be used as a donor for at least two years after leaving the zone, provided that he discontinued suppressive treatment (atabrine or quinine) then and has not had any recurrences of malaria for at least two years previous to his donation. Before donation a thick smear should be examined and found to be negative.

Rule 2. If the prospective donor has been in a malarious area and has not had any attack of malaria and for the past year has not taken any suppressive treatment, he may be used, provided a thick smear does not reveal any parasites. The history of undiagnosed fever or a questionable history should cause the application of rule 1.

Even these rules may not prevent an occasional transfer of the disease but they are considered sufficient to serve as general rules. If about a week

CYSTIC FIBROSIS OF THE PANCREAS

T. B. MERNER, M.D., J. F. BOSMA, M.D., and A. J. MOSS, M.D.
Minneapolis, Minnesota

THE purpose of this presentation is to call attention to a clinical entity which, though adequately described only recently, is encountered with surprising frequency in the practice of pediatrics. Eight typical cases of this disease, cystic fibrosis of the pancreas, have been selected from those observed at the University of Minnesota Hospitals during the past few years to illustrate its known clinical and roentgenological characteristics.

Since one of the principal characteristics of the disorder is the occurrence of an excess of fat in the stools, it must be distinguished from the more familiar "celiac disease," or idiopathic steatorrhea, with which it was formerly confused. Children suffering from either of these conditions present the same clinical characteristics of bulky stools, enlargement of the abdomen, and signs of nutritional deficiency. Those with cystic fibrosis of the pancreas, however, actually suffer from a generalized disorder, one of the striking manifestations of which is chronic disease of the respiratory tract.

The co-existence in certain children of severe respiratory infection and a celiac-like picture was first described in 1913 by Garrod and Hurtley.[9] The first observation of pancreatic disease in these children was made in 1919 by Passini[14], who described the typical findings of cystic fibrosis of the pancreas in a child who had had abnormal stools since birth, and who died of bronchopneumonia at the age of nine months. A similar pancreatic lesion was found in a sibling of this child who died during the second month of life.

Sporadic reports of this coincidence of steatorrhea with respiratory and pancreatic disease continued to appear in the literature until 1938, when Andersen[2] published a series of forty-nine pathologically proved cases of cystic fibrosis of the pancreas, twenty of which she had found among the material of 605 autopsies at Babies' Hospital in New York City. Andersen classified these into three groups according to the period of their survival. In 10 per cent of the children death occurred within a few days of birth due to obstruction of the intestine by an unusually viscid meconium. Sixty per cent of the infants developed respiratory infections, and died before the age of six months. The remaining 30 per cent survived for longer periods with a uniform coincidence of chronic respiratory disease and malnutrition. The surprising incidence of this supposedly rare condition was later verified by Farber[8], reporting the autopsy findings of eighty-seven cases. Smaller series were reported by Snelling[17], Daniel[7], and Shohl.[16]

Etiology

The etiology of this condition remains obscure. Accumulated evidence is much in favor of its congenital origin in the great majority of children. In many instances the condition is obviously present at birth. It frequently occurs in several siblings. Kennedy and Baggenstoss[12] described a typical patient having cystic fibrosis of the pancreas, five of whose eight siblings died before the age of eight months with the symptoms of chronic cough and diarrhea.

The atrophy and cystic degeneration of the exocrine parenchyma of the pancreas, and the increase in its interstitial fibrous tissue are found to be proportionate to the degree of occlusion of the duct system of the pancreas, and are probably secondary to it. Andersen has interpreted this occlusion as an anomaly of development. She suggested that the nutritional deficiency incident to the loss of pancreatic function is the cause of the other manifestations of this disease. The severity and chronicity of the respiratory infections were related particularly to a deficiency of vitamin A.

The absorption of vitamin A is also impaired, however, in children with the classical celiac disease. This latter category of patients has a greater than normal susceptibility to minor respiratory infections, but there is an obvious distinction in the severity and chronicity of the respiratory disease as it occurs in each of these two conditions. Andersen[2] has placed much emphasis upon the hyperkeratoses which she has found in some of these patients as an evidence of a deficiency of vitamin A. Farber[8] was able to find such changes in but

---

From the Department of Radiology and Physical Therapy and the Department of Pediatrics, University of Minnesota.

a few instances in his larger series of postmortem examinations of these patients.

The most acceptable explanation so far offered is that of Farber[8], who points out that the secretions of all of the mucous-secreting organs of these patients are characteristically viscid, and that the mechanical obstruction caused by these secretions is probably primary to the cystic changes in the pancreas, and is a prominent factor in the development of pneumonia. Obstruction of the respiratory system is now known to play a primary role in the pathogenesis of many pneumonias.[1]

TABLE I. NUTRITIONAL LOSS IN STEATORRHEA

Ingested Food	Fecal Loss	Clinical Manifestation
Neutral fat.....*Fatty acids and soaps		Large, odorous stools Protruberant abdomen Caloric deficiency
Carbohydrates*	Significant loss only in exacerbation	
Proteins*		
Fat-soluble vitamins		
Vitamin A	+ —	Keratoses (infrequent)
Vitamin D	+ —	Osteoporosis, rickets
Vitamin K	?	No evidence of deficiency
Vitamin E	?	
Water-soluble vitamins		
Vitamin B	?	
Vitamin C	?	
Minerals

Iron ....Soaps (insoluble)	+	Hypochromic anemia
Sodium ....Soaps (soluble	Significant loss only in exacerbation	
Potassium ....Soaps (soluble		
Water		

*Digestion impaired in cystic fibrosis of the pancreas, with loss of unsplit fats, carbohydrates, and proteins.

The loss of various dietary factors which occurs in steatorrhea of any form is summarized in Table I. Comparative studies of the nutritional loss in ideopathic steatorrhea and that associated with cystic fibrosis of the pancreas have yielded variable results. It may be stated that in general there is an increased fecal content of partially digested lipids, proteins, and carbohydrates, in this latter entity.

The steatorrhea found in these patients is analogous to that described by Vermeulen, Owens, and Dragstedt[19], and by Coffey and Mann[6] in depancreatized dogs. In carefully controlled metabolic experiments it was found that these animals suffered an increased loss of fecal fats, both whole and hydrolyzed, with a smaller and more variable loss of protein and carbohydrate.

Clinical Characteristics

A part of the relevant data on the eight patients selected to illustrate this discussion is summarized in Table II. The classification suggested by Andersen has been followed in this table.

The clinical picture of the newborn infants having meconium ileus is entirely different from that of older children with cystic fibrosis of the pancreas, though the autopsy findings are similar. These infants have the typical clinical evidences of intestinal obstruction, with abdominal distention, vomiting, and absence of stools. Surgical exploration reveals an elongated mass of adherent gelatinous meconium occluding a portion of the lower intestine, which is collapsed distally to this site. These infants usually expire from meconium peritonitis or pneumonia within the first few days of life.

A summary of the essential data in a typical case illustrating this group follows:

Patient D. R. was born of a normal pregnancy. The birth weight was 8 pounds, 7 ounces. No meconium was released per rectum. Persistent vomiting developed shortly after birth, an abdominal distention appeared at twelve hours of age. The patient was admitted to University Hospital on the second day of life.

This patient was the fifth child, and two siblings were living and well. One sibling had intestinal obstruction which was relieved spontaneously on the third day of life, but an alimentary disturbance, with episodes of vomiting, persisted. The child died of pneumonia at the age of three months. The fourth sibling also had an intestinal disturbance, with passage of bulky stools. She developed a chronic cough at the age of three months, and died of pneumonia at four months.

By digital examination, the rectum was found to have a very small lumen. An x-ray film of the abdomen showed the stomach and intestine to be markedly distended. A laparotomy was performed on the third day of life. The distal ileum was found to be distended with viscid meconium, and the colon collapsed to a mean diameter of 5 to 7 millimeters. An ileostomy was performed. The patient developed persistent respiratory difficulty with cyanosis and died on the fourth day of life.

TABLE II

Patient Age at Observation	Nutritional State	Size of Abdomen	*Steatorrhea* Char. of Stools	Fecal Fat (% Dry Weight)	Respiratory Infections	X-ray Findings in Chest	Duodenal Aspir. (Trypsin Activ.)	Sibling History
Group I								
1. D.R.* 3-4 day	"Good"	....	....	....	....	—	....	2d. pneumonia *(1) in infancy
Group II								
2. S.S.* 4 mo.	"Well nourished"	....	Bulky, odorous	....	Pneumonia at 3 mo.	+	....	1—d. pneumonia in infancy* 1—normal
Group III								
3. M.M.* 5-11 mo.	"Markedly thin"	Large	Bulky, odorous	35	Pneumonia at 5, 8, 10 mo. Chronic cough	+	Absent	1—d. pneumonia in infancy 1—chronic cough 1—"celiac disease" 1—rickets 3—normal
4. J.G. 3-12 mo.	"Emaciated"	Large	Bulky, odorous	....	Persistent "colds"	—	Absent	3—normal
5. E.S.* 3 yr.	"Markedly undernourished"	Large	Bulky, odorous	38	Pneumonia at 6 mo. 2 yr.* Chronic cough.	+	....	2—d. pneumonia in infancy
6. P.N. 4-5 yr.	"Undernourished"	Large	Bulky, odorous	45.1	"Colds," pneumonia at 2 yr.	+	Absent	2—normal
7. D.S. 5-6 yr.	"Emaciated"	Large	Bulky, odorous	53	Bronchitis at 1½ yr. Chronic cough.	+	Absent	2—normal
8. J.J. 6-7 yr.	"Emaciated"	Large	Bulky, odorous	++++ (stain)	Pneumonia at 6 yr. Chronic cough.	+	Absent	No siblings

Autopsy revealed an increased amount of thick mucus in the bronchi and bronchioles. Microscopic study of the pancreas revealed a striking degree of atrophy of the exocrine parenchyma and an apparent increase in the amount of connective tissue. The small and large ducts were dilated and filled with homogeneous eosinophilic material which histologically had the appearance of inspissated secretion.

Andersen's differentiation of the second and third groups of these patients is based upon their survival for less or more than six months. This division is somewhat arbitrary. A typical example of the patient in each of these categories follows:

Patient S. S. was admitted to the University Hospital at the age of four months with a history of chronic cough, difficult feeding and weight loss of two weeks' duration.

The patient had one well sibling. A previous child had died at the age of seven months after a similar episode of chronic cough and digestive disturbance. Postmortem examination of this sibling revealed bronchopneumonia and the characteristic findings of cystic fibrosis of the pancreas. The family history was otherwise non-contributory.

At the time of the patient's admission the physical findings were essentially negative, except for the observation of a mild dyspnea and the presence of coarse râles distributed diffusely over the lung fields. During the three weeks of hospital care the chronic cough increased and became paroxysmal in nature. The respiratory difficulty was progressive, with the development of severe inspiratory retraction and persistent cyanosis. Successive chest roentgenograms revealed a persistent emphysema, with increasing bronchial markings suggestive of bronchitis or bronchiectasis. Direct laryngoscopy disclosed no significant pathology. Sulfadiazine therapy, intravenous aminophyllin and steam were of no benefit. Despite continuous administration of oxygen, the child expired.

Autopsy revealed a large amount of muco-purulent material in the bronchial tree. Microscopic examination of the lungs demonstrated a moderate bronchiectasis and a severe peribronchial pneumonitis. (Fig. 3). The pancreas showed an early typical cystic fibrosis (Fig. 2).

Patient J. J. had been chronically ill for several years. Episodes of diarrhea and recurrent alimentary difficulties had been present since the second year. The patient had been thin and pale and had enlargement of the abdomen for an indefinite period. He had a chronic non-productive cough since the age of four years. He was admitted to the hospital at the age of six years for therapy of a bronchopneumonia which appeared as a complication of measles.

There were no siblings of this child. The family history was otherwise noncontributory, except for the mother's admission that her diet had been inadequate during her pregnancy.

At the time of admission the boy weighed thirty-four pounds. His appearance was that of emaciation and chronic illness. He was slightly dyspneic and cyanotic. The chest was emphysematous and coarse râles were heard diffusely within it. The abdomen was protruberant and of a doughy consistency on palpation.

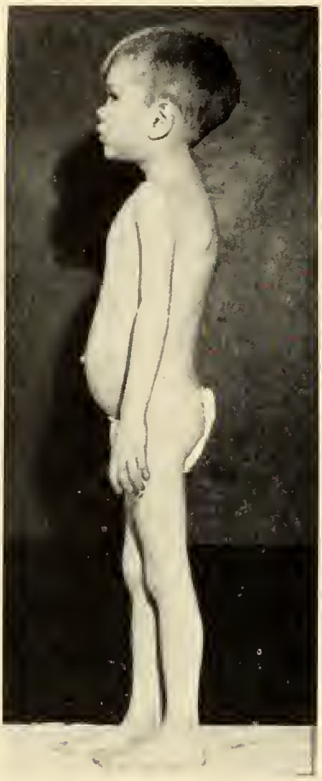

Fig. 1. Patient D. S. The wasting of the extremities, the protruberant abdomen, and the increased antero-posterior diameter of the chest are demonstrated.

Laboratory studies demonstrated a persistent leukocytosis and elevation of the sedimentation rate. The stool fat was found to be much increased by qualitative test. Duodenal aspiration revealed an absence of trypsin activity in the pancreatic juice. The glucose tolerance curve was low. X-ray examination of the chest showed moderate emphysema, a marked increase in broncho-vascular markings, and evidences of bronchopneumonia.

The response to sulfadiazine and penicillin therapy during the three months' period of hospitalization was very slow. The dyspnea was slowly relieved, and the roentgenological findings of pneumonia gradually resolved. The chronic cough and the findings of râles scattered diffusely throughout the lung fields persisted.

Subsequent observations in the Out-patient Service reveal that the condition of this patient is essentially unchanged, despite parenteral vitamin A therapy, oral vitamin B, high protein diet, and periodic postural drainage. He remains thin and pale, and has a persistent cough which is productive of a little mucopurulent sputum. He continues to have intermittent episodes of fever, and is confined to bed much of the time.

The presenting complaints made by the parents of these patients may refer primarily to either the nutritional disturbance or to a respiratory infection, although both alimentary and respiratory disease are commonly present. In the case of younger infants, the failure of growth is neglected, and the usual principal complaint is that of chronic cough, or of the symptoms of a recurrent pneumonia. During later infancy and the preschool years physical retardation is more apparent and these children are brought for medical attention because of marked dwarfism, with their chronic cough occupying a secondary place in the parents' interest.

Data regarding the physical retardation of these patients are recorded in Table II, with comments on the nutritional state of each patient at the time of admission to the hospital. The only patient who had not suffered a marked loss of physique was Patient S. S., who appeared "well-nourished." Further review of her record, however, reveals that her weight had increased but two pounds above birth weight in her four months of life, despite an apparent adequate diet, and her weight of ten pounds at the time of hospital admission was four pounds less than the average for her age.

Much of the reason for the failure of these children to grow normally is revealed in the column "Steatorrhea" of Table II. The observations of distinctively bulky and odorous stools in all of these patients and that of abdominal enlargement in six of the seven would lead one to suspect the presence of steatorrhea. This suspicion was verified quantitatively in four patients and qualitatively in one by the observation of a greater than normal loss of lipids in the feces.

These children are peculiarly susceptible to chronic respiratory infection, with progressive secondary emphysema and bronchiectasis. The infections are highly resistant to therapy, and a febrile state may persist for months, during which time the patient coughs up quantities of thick mucopurulent sputum. The accumulation of the typical viscid bronchial secretions often causes episodes of dypnea and wheezing, as reported in six of our eight patients. In two of these the mistaken diagnosis of pertussis had been made upon the basis of these symptoms. The respiratory obstruction and the increasing emphysema may combine to cause a persistent respiratory deficiency with cyanosis.

Episodes of bronchopneumonia may be superimposed upon this chronic respiratory disease, and are usually responsible for the death of the patient.

A great deal of emphasis has been placed upon the family history as an aid in the diagnosis of this condition. With the exception of a few rare instances in which a maternal intolerance to fat was suspected, the only significant coincidences found by others were in the occurrence of like disease in the siblings of the patients. This coincidence was found in siblings of four of the eight patients described here.

We may summarize the clinical picture as one consisting of a chronic intestinal disturbance, with secondary growth failure and an associated persistent respiratory infection. We would like to emphasize the commonness of each of these complaints in pediatric practice. In clinical examination, without the aid of laboratory procedures, the presence of this systemic entity of fibrocystic disease could easily be undetected.

Laboratory Examinations

1. *Evidence of Steatorrhea.*—The presence of steatorrhea is confirmed by the findings of an increased amount of lipid in the dried stool. The most valid data in this determination is that obtained on the total stool collected over a period of several days, during which the patient is on a normal diet.

The distinctive proportion of neutral fat in the stools, which has often been thought diagnostic of cystic fibrosis of the pancreas, in distinction from idiopathic steatorrhea[11,16], has not been prominent in our patients. In the patient E. S., for instance, neutral fat comprised but 28 per cent of the total fecal lipid. It is the conclusion of Andersen[2] that the proportion of neutral fat in the total fecal lipid is highly variable, and cannot be used as a basis for differentiation of idiopathic steatorrhea from that associated with pancreatic disease.

2. *Evidence of Pancreatic Deficiency.*—The single laboratory test, other than roentgenological studies, which provides a valid basis for the diagnosis of cystic fibrosis of the pancreas in the living patient is the analysis of the pancreatic juice, as obtained by duodenal aspiration. Adequate precaution must be taken in the procedure of obtaining this material, to insure that it is obtained from the duodenum. The aspiration tube should be perforated only within a few inches of its tip, and it must be shown by fluoroscopy to be in the second portion of the duodenum. The most accurate index of the functional capacity of the pancreas is obtained when the organ is stimulated, as by the instillation of a small amount of hydrochloric acid into the tube, or by the intravenous administration of a highly purified secretin preparation.

The content of trypsin in the pancreatic secretions is most commonly analyzed. Its content is evaluated by the lysis of a gelatin substance in successive dilutions of the aspiration material, after the method of Andersen.[2]

3. *Evidence of Infection.*—The white blood count and sedimentation rate are persistently elevated in these patients, manifesting the chronicity of their respiratory infections. Cultures of the sputum during the acute episodes of bronchopneumonia yield staphylococcus aureus with great consistency. This organism was found in six of the seven patients from whom throat cultures were taken.

Pathology

The essential pathology according to Andersen[2] is in the pancreas and the pulmonary changes are secondary, due possibly to nutritional deficiency. The systemic nature of this disease, however, is very striking, and the pancreatic findings are only part of the whole picture. Farber[8], in a recent review of the autopsy findings on eighty-seven cases of pancreatic fibrocystic disease, describes the uniform presence of a homogeneous sticky material in the trachea, bronchi, bile ducts, salivary glands, and pancreas. He believes the inspissation of this material in the ducts causes the characteristic secondary changes, which will now be detailed.

1. *Pancreas.*—On gross examination, lobulation of the pancreas due to contraction of fibrosed areas below the surface of the gland was frequently found. Dilatation of the ducts and plugging of their lumina with the inspissated material previously described was common. Dilatation of the small ducts gave the pancreas a cystic appearance. Atrophy of the exocrine parenchyma of the organ was usually present, with an increase in its interstitial structure due to fibrosis (Fig. 2).

The degree of involvement of the pancreas

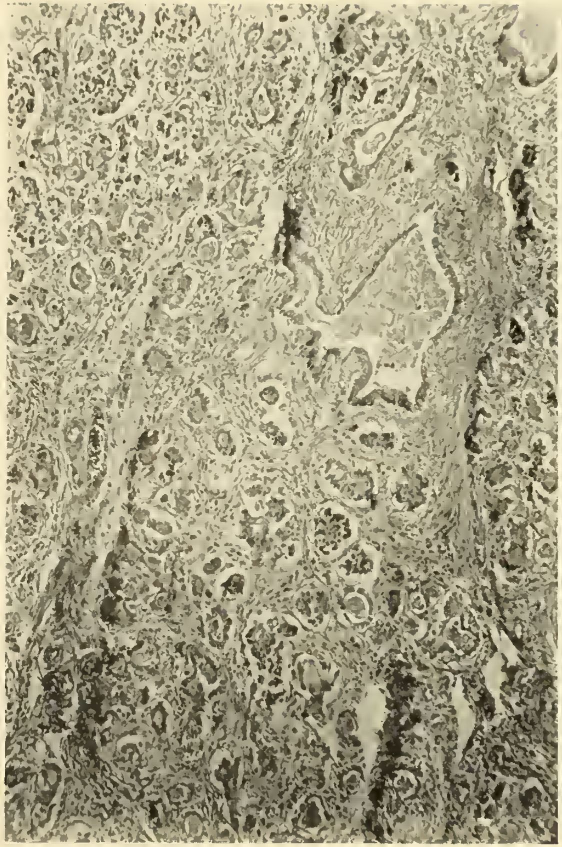

Fig. 2. Patient S. S. Section of pancreas. Marked dilatation of pancreatic ducts and plugging with inspissated mucus. The normal acini are largely destroyed and mucoid material fills the lumina. There is marked interstitial fibrosis. The islets of Langerhans appear normal.

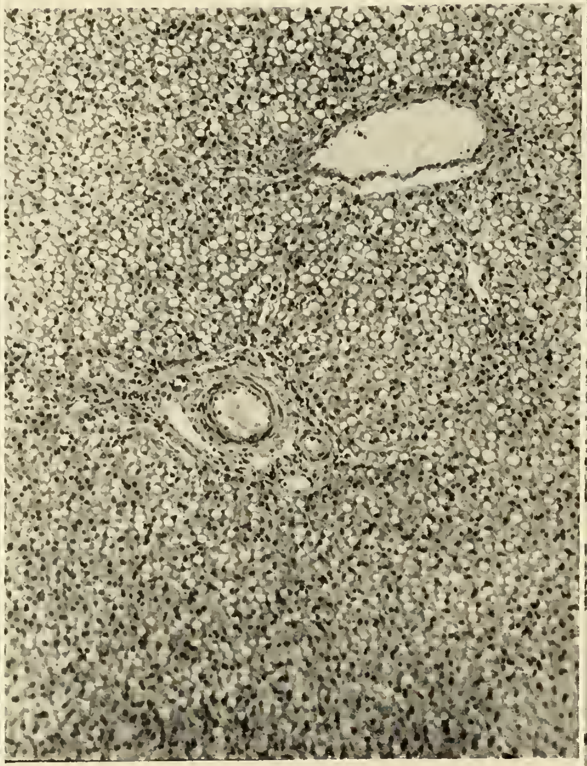

Fig. 3. Patient E. S. Section of liver. Marked degeneration of liver and fatty replacement.

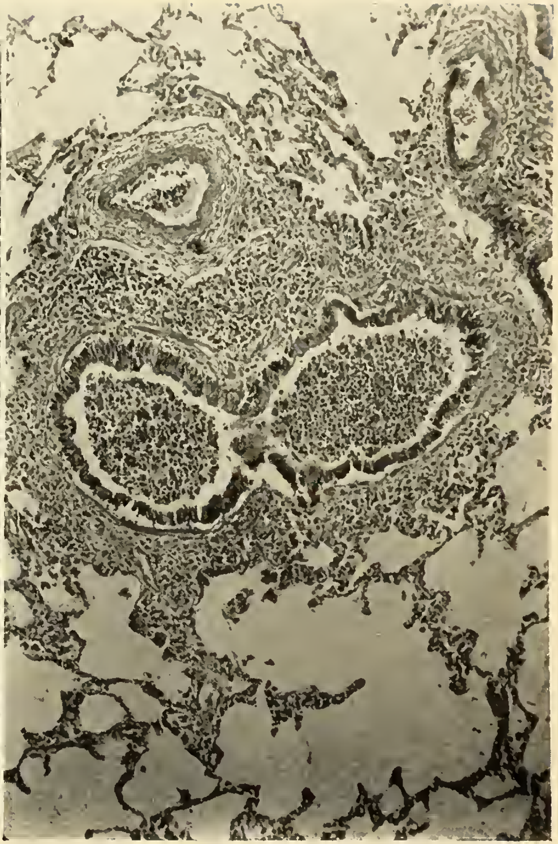

Fig. 4. Patient S. S. Section of lung. Partial destruction of bronchial wall and plugging of bronchial lumen with thick mucopurulent material. Marked peribronchial infiltration is present and there is relatively little fibrosis. Note the surrounding areas of emphysema and destruction of alveoli.

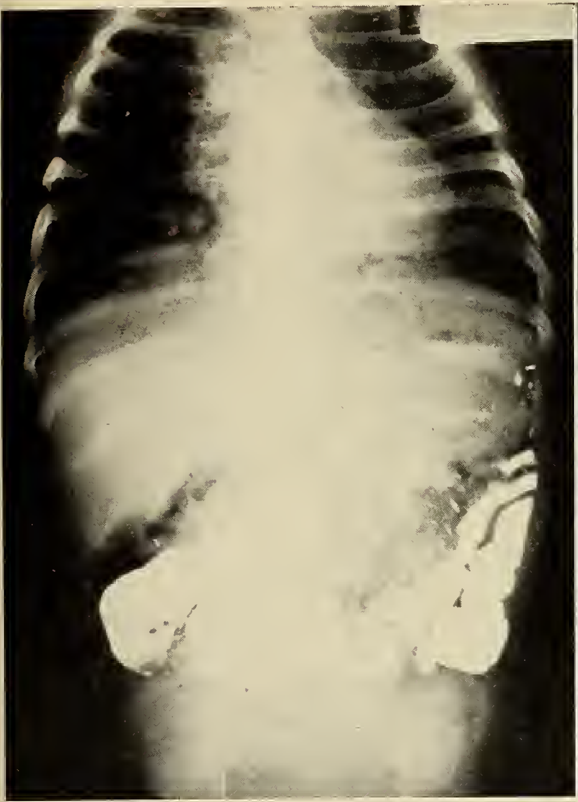

Fig. 5. Patient M. M. Roentgenogram of chest and stasis-ray examination of small bowel. Pulmonary changes are similar to those in Figure 6. The distinctive "segmentation" of the barium meal in the small intestine is indicative of steatorrhea.

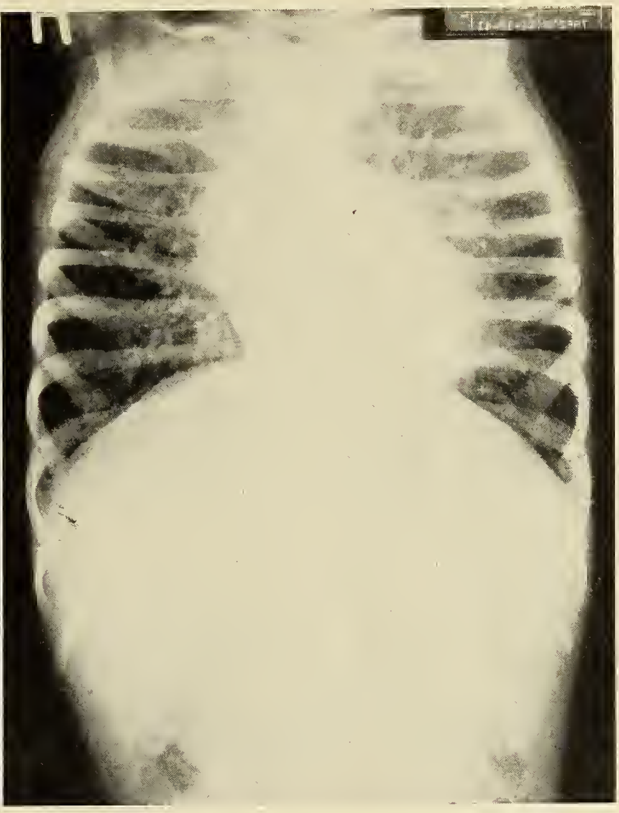

Fig. 6. Patient E. S. Roentgenogram of chest. Diffuse peribronchial infiltration accentuated about the hilum and extending in linear manner peripherally. Marked peripheral emphysema, demonstrated by depressed diaphragm and increased radiolucency. The areas of consolidation near the left hilum represent bronchopneumonic patches.

varied greatly. In cases with minimal involvement the only finding was occlusion of the ducts and acini, with no atrophy. It should be noted, however, that even in these minimal cases usually no trypsin was found in the duodenal contents. The islets of Langerhans were not involved.

2. *Liver.*—The liver was often larger than normal, and contained varying amounts of fat. The degree of fatty degeneration seemed to vary directly with the amount of pancreatic destruction (Fig. 3).

3. *Respiratory Tract.*—In each of the forty-nine cases in Andersen's original series there were changes in the respiratory tract. There was mild tubular dilatation of the small bronchi and bronchioles, with plugging of their lumina with tenacious purulent material. In some cases these bronchiectatic changes were very marked. Often there were multiple abscesses arising in the small bronchi, and the trachea also contained sticky mucopurulent material. At times the appearance suggested that the patient must have experienced suffocation due to the abundance of the exudate.

Pulmonary fibrosis in our cases was very minimal, less than would be expected with such a marked amount of chronic inflammation (Fig. 4).

Roentgenological Findings

1. *Small Intestine.*—According to Golden[10], the small intestine of newborn infants frequently presents a different appearance on examination with barium to that found in older children. Apparently due to a lack of nervous reflex control, areas of spasm alternating with areas of dilatation are present. 'A "segmentation" effect results; another term used in respect to this appearance is a "puddling" formation.

This effect is greatly accentuated in nutritional disturbances. Vitamin deficiency, especially lack of the vitamin B complex, apparently plays an important part in the production of the intestinal changes seen in steatorrhea. In the nutritional deficiencies, there is considerable thickening of the mucosal folds with elimination of the normal fine mucosal pattern. There may be merging of the folds due to this thickening, resulting in a smooth appearance of the mucosa. This effect is most noticeable in the jejunum because the folds are normally more prominent here than in the ileum.

Hypomotility is another prominent feature. Normally the barium passes through the small bowel into the cecum in three to six hours. In many cases of steatorrhea, passage is delayed for as long as eight or ten hours.

The above changes are not specific for the pancreatic type of steatorrhea. They are present also in ideopathic steatorrhea. Figure 5 illustrates these findings as observed in patient M. M.

2. *Chest.*—The appearance of the disease in the chest roentgenogram is somewhat characteristic, although it may be simulated by other conditions when still in its early form. Certain features are strongly suggestive of the presence of the disease.

The distribution of the changes is rather uniform and widespread, involving all lobes of both lungs equally.[4] Concentration of the lesions is greatest about the hilar regions with loss of the normal vascular markings. Mottled linear shadows fade out toward the periphery where they are gradually lost in the areas of peripheral emphysema. These linear densities are often misinterpreted as representing fibrosis. They are in fact due to the marked peribronchitis and bronchopneumonia (Fig. 6).

Frequent acute episodes of bronchopneumonia occur which leave permanent damage to the lungs. Bronchopneumonia is shown on the films by consolidations of various sizes found more commonly in the perihilar regions.

Bronchiectasis of an atypical type is one of the most characteristic features. It is very diffuse and involves the upper lung fields as well as the bases. A final diagnosis of bronchiectasis can only be made by a bronchogram. The importance of the frequency of occurrence of bronchiectasis in this disease was stressed by Andersen. Of eight children who died of bronchiectasis in the first year of life, seven had definite cystic fibrosis of the pancreas.

Atelectasis occurs frequently as a result of complete obstruction of a bronchus. A local area of homogeneous density with retraction of the mediastinum or elevation of the diaphragm is sometimes seen on the film.

Emphysema is quite marked and is much more apparent in the peripheral areas. The rib interspaces are widened and the diaphragm on both sides is depressed (Fig. 6). Emphysems is due to partial bronchial obstruction.

3. *Differential Roentgenological Diagnosis.*—The disease can be distinguished from bronchopneumonia by its lack of definite consolidation, by its diffuse character, and its extreme chronicity. Bronchiectasis in the ordinary form has a tendency to distribute itself in the lower lung fields. Bronchial asthma resembles this disease very closely in the chest film. The picture as seen in cystic fibrosis of the pancreas is distinguished by greater relative density of the hilar shadows.

In summary, the pulmonary changes in cystic fibrosis of the pancreas are quite characteristic. The disease is diffuse, is of chronic nature, and appears to be progressive. Mottled densities are seen in both hilar regions extending in streaked fashion into the peripheral areas of emphysema. The findings are sufficiently suggestive to be recognized in the chest roentgenogram, and other diagnostic procedures should then be carried out.

Therapy

The therapy of this disease has so far been disappointing. The intestinal symptoms and the nutritional loss are improved by a diet low in fat and high in protein. An excellent dietary regime for these children including specific mineral and vitamin supplements, has been recently outlined by Andersen.[3] The chronic pulmonary condition is benefited by periodic postural drainage. With the use of penicillin therapy these children now frequently survive the recurrent episodes of pneumonia to which they usually succumbed. The importance of vitamin A in the etiology of the respiratory disease has been emphasized by Andersen. We therefore have given massive doses of parenteral vitamin A, but have not found it to be of specific value.

The greatest known age of survival at the present time is fourteen years.[13]

Summary

Cystic fibrosis of the pancreas is a systemic disease which is more prevalent than is generally recognized. It manifests itself clinically by stea-

(Continued on Page 453)

A NEW METHOD FOR CUTTING FULL-THICKNESS OR SPLIT-THICKNESS SKIN GRAFTS

ALBERT E. RITT, M.D.
Saint Paul, Minnesota

For many years, it has been my good fortune to have a fairly representative industrial service as part of my general practice.

Many of the injuries have been concerned with finger-tip defects caused by punch presses, circular and handsaws, planers, and similar pieces of mechanism. In many instances, the injuries have been clean-cut, partial amputations either through the soft tissue portion of the finger alone, or through various portions of the bony part of the digit. In all instances, it has been my desire to preserve as much length of the finger as possible.

Where feasible, a skin graft has been the answer to this problem. In many instances, I have found it convenient to use some variation of a circular skin graft or flap to close such defects. Up to the present time, it has been time saving for me to use the patient's thigh on the side of the injury as the donor site.

Grafts cut according to a muslin or gauze pattern, in my experience, have not been too satisfactory. It must be remembered that grafts shrink in size up to 20 or 30 per cent, and it is therefore understandable that a circular graft is more adaptable to be patterned than a more regular-sided one.

The method which seems to greatly simplify, speed up, and generally improve the procedure, is as follows:

1. Prepare the donor site, according to the accepted methods.
2. Estimate the size of the graft needed by placing over the defect to be closed the thumb opening of a forceps.
3. Using the handle of this forceps as a stabilizing unit, place the fenestra or thumb opening firmly on the donor site.
4. Using a scalpel with a No. 15 blade, incise the skin on the inside of the fenestra or thumb opening following the inside perimeter of the opening.
5. Cut to desired depth by varying the pressure on the scalpel.
6. Pick up circumscribed or delineated skin with a light grasping forceps.
7. Undercut base.
8. Dust base of graft with sulfa powder and place on wet normal-saline pack.
9. Sew selected graft to previously prepared site.
10. Cover both donor and recipient sites with vaseline gauze and a generous pressure dressing.
11. Bandage with an elastic type of bandage or tape.

If it is felt that a larger graft should be taken than is provided by the size of the thumb opening in the forceps, then a semicircular cut may be made from one end of the forceps, the forceps moved, and the semicircular cut completed. Each half may then be joined by following a straight edge of the forceps.

In a similar manner, an elliptical or smaller graft may be made.

MINNESOTA GIVES $7,065,365 IN THE THREE WAR YEARS

Minnesota citizens united gloriously to give a total of $7,065,365 for our own and for our allies in three war campaigns of the Minnesota War Service Fund, figures compiled from county chairmen's reports to state headquarters show.

For three successive years, Minnesota raised 100 per cent of its National War Fund quota for USO, War Prisoners' Aid, United Seamen's Service and the relief agencies of our allies. It was one of a very few states in the nation to go over the top all three years.

Under the leadership of J. Cameron Thomson, state chairman, a board of trustees representing various sections of the state and volunteer chairmen in every county, Minnesota won a national reputation in federated wartime giving.

Home Front Added

Along with the more than $7,000,000 raised for national wartime agencies, Minnesota citizens contributed at the same time in united campaigns for local agencies a total of $9,479,978.

Thus through the war years, Minnesota citzens gave $16,554,240 for our men in service, for our allies and for the home front.

1945 Campaign

In the 1945 campaign, a total of $2,088,026 was contributed—$1,206,428 by the three metropolitan areas and $881,598 by out-state counties.

51 Counties Over

Fifty-one campaign units in this last campaign reached or exceeded their goal. Despite the indifference toward such wartime campaigns engendered by the coming of peace a month and a half before the opening of the campaign, the state made a great record and the 40,000 workers who carried on the campaign worked tirelessly to put the drive over.

Only eight other states in the nation reached their National War Fund goal in the 1945 campaign, William C. Walsh, campaign director, reported, and of these, Minnesota had the largest quota. Only one other—Iowa—had a quota of more than $2,000,000.—*News Bulletin,* April 24, 1946 (Minnesota War Service Fund)

CLINICAL-PATHOLOGICAL CONFERENCES

DIAGNOSTIC CASE PRESENTATION

ARTHUR H. WELLS, M.D., and L. L. MERRIMAN, M.D.
Duluth, Minnesota

Dr. L. L. Merriman: A sixty-four-year-old white male clerk (Case 2243) was admitted to the hospital two weeks before his death complaining of severe dyspnea. He had had pneumonia with emphysema almost thirty years ago. Ever since that time he had noticed dyspnea with slight exercise. This was at first of a minor character but gradually progressed, especially during the past five years, until at present it causes him considerable discomfort. For example, he has to pause while firing the furnace between shovels of coal to catch his breath. The dyspnea has been worse during the winter months. He has noticed no particular association with food, clothing, animals, seasons, et cetera. He has had no precordial pain, palpitation, nocturnal dyspnea, or edema. When he stopped smoking five years ago, a chronic cough productive of whitish sputum disappeared. There was no further coughing until the onset of a "cold" about one and one-half months prior to his death. His past medical and social history were essentially normal. His father and a brother died of pneumonia. The physical examination revealed a mentally alert, co-operative, slenderly built, severely dyspneic, weak man of sixty-four years with a normal temperature, blood pressure of 105/75, pulse 85, and respiration 25 per minute. The chest was "barrel-shaped" and had diminished respiratory expansion. Breath sounds were diminished and there was hyperresonance throughout the thorax. There was a hacking cough productive of thick yellowish sputum. There was no detectable movement of the diaphragm. A few bronchial râles were heard. There was no wheezing. The size and rate of the heart were normal. Its sounds were distant. There were no murmurs. The pulse and peripheral blood vessels were normal. The second pulmonic sound was accentuated. There was no evidence of chronic congestive heart failure. An electrocardiogram (Fig. 1) was interpreted as evidence of myocardial disease of indeterminate type. A roentgenogram (Fig. 2) was interpreted as showing pulmonary emphysema, scoliosis of the thoracic spine, old, healed, fibroid tuberculosis of the right upper lobe with calcified hilar lymph nodes on the right. In the laboratory, the examination of many sputa failed to reveal acid-fast bacilli. The red blood cell count was 5 million, and the white blood cell count was 9 thousand to 15 thousand with moderately increased percentage of neutrophils. The red blood cell sedimentation rate was 10 mm. in one hour. The basal metabolism rate was plus 13 and the Kline test was negative.

During the two weeks in the hospital preceding his death, he suffered almost continuously from dyspnea which was only partially relieved with oxygen and helium therapy along with aminophylline and supportive measures. Talking or slight exertion markedly aggravated both dyspnea and coughing. Brief spells of relief were invariably followed by attacks in which there was extreme anxiety in an effort to breathe enough air to exist. Every muscle in his body appeared to be taking part in this desperate need for oxygen. There was a continuous, mild but definite cyanosis of his lips and finger nails. His condition had shown no improvement up until the time he was found sitting in a chair dead.

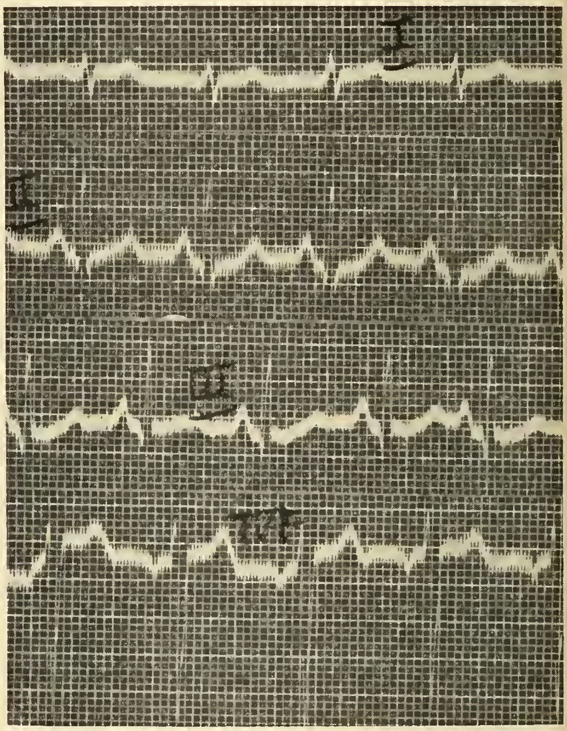

Fig. 1

The case is now open for diagnoses.

Physicians: Ayerza's disease. Coronary thrombosis. Pulmonary emphysema with right heart failure. Thrombosis and partial occlusion of the pulmonary artery. Chronic myocarditis. Congenital cardiac anomaly.

Autopsy

Dr. A. H. Wells: The diagnosis of Dr. F. J. Hirschboeck is correct. The autopsy examination revealed a

From the Department of Clinical Pathology, St. Luke's Hospital, Duluth, Arthur H. Wells, M.D., Pathologist.

grade IV pulmonary emphysema uniform throughout all lobes of both lungs, associated with a mild suppurative chronic bronchitis, a mild bronchiectatic dilatation of delicate walls of the small bronchi beginning in the third branches and complicated by a mild cor pulmonale with chronic passive congestion of the liver and spleen. There were only mild toxic changes in the myocardium. The coronary and other arteries of the body were in excellent condition. The microscopic examination of the lungs revealed a low grade chronic inflammatory process in the walls of the larger bronchi. Their epithelium was intact. There was considerable dilatation of most of the air passages of all sizes with a decreased breadth of their walls. Occasionally the smaller air passages were normal in size. The respiratory bronchioles, alveolar ducts, atria, air sacs, and alveoli were uniformly and severely dilated throughout all of the sections. Their walls generally formed delicate strands of tissue containing very few red blood cells. The arterioles had mildly thickened walls. There were no inflammatory cells outside of the few found in the larger air passages.

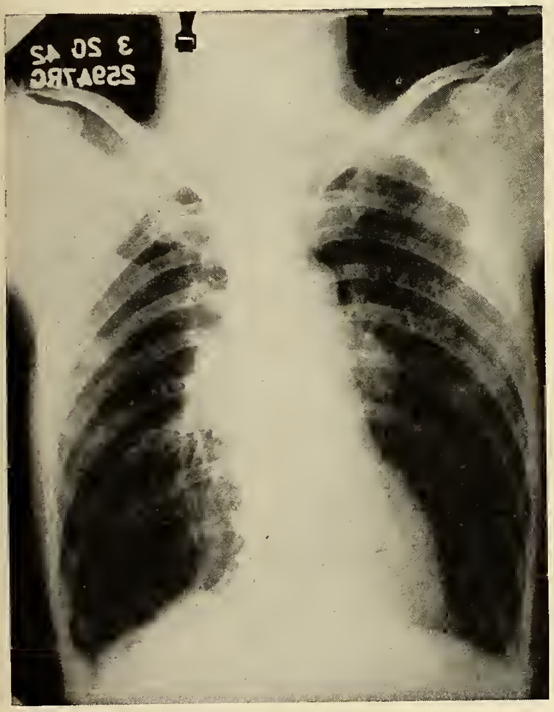

Fig. 2

In conclusion, it is my opinion that the immediate cause of death was acute right heart failure, the result of chronic pulmonary hypertension caused by extreme pulmonary emphysema, initiated as a complication of pneumonia thirty years previously, and aggravated by recurrent bronchitis.

Discussion

Emphysema may be defined as an overdistension of the primary lobules of the lungs. This broad definition is necessary to include certain cases of acute reversible emphysema. In the more important group of chronic emphysema there is a widely varied etiology with, in most instances, a constant functional change dependent upon a loss of elasticity in the lung tissues with increased intrapleural pressure, increased pulmonary residual air, decreased tidal air efficiency, and atrophy of stretched hemo-respiratory surfaces. As a group, pulmonary emphysema is among the most frequent of human illnesses. In general its frequency and severity greatly predominates in the made sex. The classifications of pulmonary emphysema in common use are a mixture of confusing clinical, pathological, etiological, and physiological manifestations. Although there is no general agreement concerning the etiology of even the commoner forms of emphysema, it is entirely possible to create a working classification based upon etiology.

Classification of Pulmonary Emphysema

I. Primary pulmonic emphysema
  A. Senile (degeneration) emphysema[9,35]
  B. Idiopathic emphysema[38]
II. Secondary emphysema
  A. Secondary pulmonic emphysema
1. Obstructive emphysema[7,29,32]
  a. Asthma
  b. Bronchitis
    Infectious[22,36]
    Chemical (poison gas)
  c. Stenoses of air passages[32]
    Internal or external
      inflammatory
      neoplastic
      cicatritial
      exudative
      transudative
      congestive[12]
      hyperplasias[3]
      foreign bodies[27]
  d. Intentional
    Exertion glottis closed[9]
    Glass blowing (?)[9]
    Chronic coughing[9,18]
2. Compensatory (propulsion) emphysema
  a. Surgical excisions[4]
  b. Air space consuming lesions
    Exudates[18,22]
    Transudates
    Congestion[12]
    Neoplasm
    Silicosis
    Fibrosis
    Cysts
  c. Atelectasis
    Air passage obstructive
      neoplasm
      exudate
      transudate
      inflammation
    Extra pneumonic
      peural fluids
      peural masses
      thoracic deformities[15]

B. Neuromuscular (hyperventilation) emphysema
  1. High altitude[8,32]
  2. Extreme exertion
  3. Emotional
  4. Paroxysms of coughing

C. Thoracic enlargement (excessive expansion) emphysema[32]
  1. Costo-vertebral deformities[2,19,20]
  2. Costo-sternal deformities

D. Cardiovascular (nutritional) emphysema[5,6,17,18,28,37]

Varying degrees of emphysema in patients over sixty years are almost as common as the finding of arteriosclerosis in postmortem examinations. This almost universal finding of emphysema in the senile must certainly be indicative of a degenerative change. Emphysema occurring at much younger ages without any previous medical history of respiratory infections, asthma, et cetera, is occasionally reported. Dr. F. J. Hirschboeck has been following identical twins, aged twenty-five, with idiopathic pulmonary emphysema. The great majority of cases of pulmonary emphysema of clinical importance in younger individuals is associated with asthma, bronchitis, and pneumonia. These conditions most likely cause the emphysema because of obstruction of either inspiration and expiration or both. The importance of years of hard labor, glass blowing, chronic coughing, et cetera, is difficult to evaluate, but these may well be contributing factors in the development of emphysema in certain individuals. When the function of a significant portion of the lung has been destroyed by any process inside or out of the lung, the remaining lung will become emphysematous. This is commonly called compensatory emphysema but might better be named propulsion emphysema. A pathologist routinely expects a severe emphysema in the uninvolved lung of an elderly patient with severe pneumonia of even short duration. Transient emphysemas are described as a result of hyperventilation, associated with high altitude, extreme exertion, et cetera. Horses develop an incapacitating emphysema ("broken wind") as a result of improper training. It is entirely possible for emphysema to result from any deformity in which the total cubic space of the pleural cavities is considerably increased. Confusion has arisen between the almost universal enlargement of the pleural cavities in other causes of pulmonary emphysema and a theoretical disease of intervertebral discs of the spine resulting in an enlarged thoracic cage and secondary pulmonary emphysema. No agreement can be found in the literature concerning the possible development of pulmonary emphysema as a result of a poor blood supply to the lung tissues. In one review of the literature of Ayerza's disease[6], the lungs were apparently surprisingly free from emphysema. It should be quite obvious that in any given case of pulmonary emphysema one might well expect a number of different causative factors.

Pathologic Anatomy

The anatomic changes in emphysema are primarily those of signifcent dilatation of the primary lobule, that is, the respiratory bronchiole, alveolar ducts, atria, alveolar sacs, and the alveoli. A dilatation of the bronchi with decrease in thickness of the walls may be noted up as high as the second division beyond the main bronchus. Secondary manifestations are the inevitable changes in the thoracic cage ("barrel-chest," dorsal kyphosis, elevation of sternum, horizontal position of ribs, separation of ribs, wide epigastric angle, ankylosis of the costo-vertebral and the costo-sternal articulations, et cetera. Also, cor pulmonale, widespread evidences of right heart failure, interstitial emphysema, emphysematous blebs, pneumothorax, and bronchiectasis are common.

The authors of several recent textbooks of pathology and the majority of authors commenting on the subject in the current literature agree to the great importance and prevalence of the pathologic feature of rupture of the overdistended, thin alveolar walls with coalescence of alveolar air sacs. This prevalent belief is probably erroneous.[14] The dangling so-called broken walls of alveoli are most likely the margins of dilated orifices of alveoli. Thick sections of lung tissue fixed in a distended condition reveal no tearing of the thin walls of terminal air spaces. The greatest distension occurs in the terminal respiratory ducts, atria, and air sacs and less in the alveoli. Emphysematous blebs are a form of interstitial emphysema and not a coalescence of alveoli.[26] There is evidence that alveolar pores may occupy as much as 50 per cent or more of the alveolar walls in emphysematous lungs.[24] Whether the very important network of elastic fibrills in the walls of terminal air spaces (primary lobules) is simply stretched or degenerated is not settled. The pathologic changes resulting from associated, causative, and complicating disease processes, such as asthma, bronchitis, tuberculosis, silicosis, bronchiectasis, et cetera, may be present in any given case. Parker[33] found in an anatomic study of thirty-two cases of "essential emphysema": 75 per cent cor pulmonale, 44 per cent right heart failure with decompensation, 80 per cent arteriosclerosis of the pulmonary artery (secondary), and 66 per cent arteriolar sclerossis ,secondary).

Pathologic Physiology

Associated with the gradual dilatation of terminal air spaces, loss of pulmonary elasticity, and gradual dilatation and fixation of the thoracic cage in the phase of inspiration, there are measurable changes in the physiologic aspects of respiration. Of the greatest importance are the changes in intrapleural pressures from a normal of minus 3 to minus 6 cm. of water to, in advanced cases, 0 to plus 2 cm. of water.[38] These changes are generally interpreted as the result of a failure of the elastic properties of the lung tissue to force out the inspired air and the assumption of this function by muscles of expiration.[9,10] The residual air may rise from 1000 c.c. to 3500 c.c. or more in emphysema. Yet the vital capacity is either reduced or requires a prolonged effort on the part of the patient to reach a normal figure. The tidal air is generally somewhat increased, apparently to compensate for a gradually increasing inefficiency. This is variously ascribed to a less effective although increased alveolar respiratory surface area, improper mixing of air in the primary lobules, and poor circulation through atrophic alveolar capillaries. A rise in the carbon dioxide tension in the air spaces coincides with its rise to over 60 c.c. per cent in the arterial blood and a corresponding oxyhemoglobin reduction to less than 80 c.c. per cent.[35] There is an associated increase in the plasma bicarbonate with a fall in the plasma chloride due to its shift into the red blood cells. A carbon dioxide tolerance is developed in the patient. As in other chronic conditions causing similar blood changes, there develops a compensatory polycythemia with red blood cell counts ranging from 5 to 6½ million. A by-product of the increased intrathoracic pressure is an interference with peripheral venous return with engorgement of veins in the neck and elsewhere. There may also be some interference with circulation of blood and lymph in the pulmonary tissue.

Clinical Recognition

The outstanding symptom in practically all uncomplicated cases of chronic pulmonary emphysema is a gradually progressing, longstanding dyspnea. Terminally this may be associated with cyanosis. The thoracic and pulmonary changes may be demonstrated by physical examination and x-ray studies but must not be confused with the thorax of hyperesthetic body build. There are the physical evidences[25,35,38] of fixation of the diaphragm, decreased or obliterated dullness over the liver and heart, prominence of cervical veins, diminished tactile fremitus hyperresonance to percussion, feeble breath sounds, prolonged expirations, feeble heart sounds, accentuated pulmonary second sound, changes in the vital capacity curve and intrapleural pressures measurements, the use of accessory muscles of respiration with slight exertion, slight differences in the circumference of the chest on inspiration and expiration, and terminally the signs of chronic congestive right heart failure. Hippocratic digits, polythemia, signs of interstitial emphysema[1,16], and spontaneous pneumothorax, may be occasionally noted.

O'Donoghue[30] lists the x-ray manifestations of emphysema: (1) general increase in brilliancy of lung fields, lack of change of radiolucency of lungs with respiration; (2) low, flat diaphragm often scalloped in appearance; (3) increased space between the heart and sternum; (4) increased prominence of pulmonary markings in the peripheral lung zone; (5) relative or absolute increase in the thickness and density of large vessels toward the root of lungs; (6) impression of smallness of cardiac shadow to increase in width of chest; (7) transverse diameter of chest in the left anterior oblique (45°) film, often actually is greater than transverse diameter of the postero-anterior film at the same level; (8) scalloped and balloned-out appearance of the soft tissues in the intercostal spaces when the chest is visualized in an oblique view; (9) flaring of the ribs with a tendency to form an obtuse angle interiorly at the costal-vertebral junction; (10) increase in the width of the intercostal spaces; (11) an abdominal enlargement of the lower thoracic cage; (12) annular shadows forming areas of radiolucency in the various parts of the lung; (13) hypertrophy of the pectoralis muscle may cause loss of translucency across the middle lung fields, the scaleni muscles similarly may cause an apparent loss of translucency at the aspices; (14) the roentgenological comparison of the cubical measurements of the chest at the height of inspiration and expiration by double exposure films reveals very little change in increased space; (15) changes seen following intratracheal injection of lipiodol have a characteristic "tattered, torn, foliage appearance."

Differentiation, of course, must be made from some of the various causes of dyspnea and cyanosis. The findings of pulmonary emphysema are so common in older patients that they are likely to be overlooked. The past medical history of the patient may give the fundamental clue as to the disease and the time of onset of the emphysema. An electrocardiogram may reveal a right axis deviation and the absence of evidence of coronary thrombosis.

Treatment

The treatment of chronic pulmonary emphysema is notoriously unsatisfactory.[9,35] Any improvement in the underlying disease process as in asthma, chronic bronchitis, etc., is paramount. Prophylactic therapy against infectious processes of the respiratory tract is indicated. Possibly the most important single procedure is a change to a warm and equable climate. Christie[10] recommends the use of an abdominal belt. In emergency situations, the use of oxygen, aminophylline, digitalis, chloralhydrate or barbiturate, and absolute bed rest have been indicated. Phlebotomy may be lifesaving. Morphine and codeine suppress cough reflexes and are contra-indicated. The training of muscles of expiration may have value. Surgical procedures aimed at mobilization of the chest have not been successful.

Summary

1. A case of pulmonary emphysema has been presented as a diagnostic problem.
2. A working classification of pulmonary emphysema based on etiology is submitted.
3. A brief review of the literature on the general subject is summarized.

SPONTANEOUS PERFORATION OF ESOPHAGUS

A. J. HERTZOG, M.D. and ROBERT LEIGHTON, M.D.
Minneapolis, Minnesota

Dr. Robert Bronson: A sixty-seven-year-old white man was admitted to the hospital on February 19, 1946. His past health had been good except for a history of a skull fracture and occasional attacks of burning substernal pain which was relieved by bicarbonate of soda. His present illness began about noon on the day of admission with a sudden attack of severe pain in his left chest. The pain occurred while walking on the street. He collapsed and was brought home in a taxi. On arrival home, his neck was found to be swollen and purple. He suffered great pain in his chest. The swelling in his neck became more pronounced. On admission to the hospital, soon afterwards his pulse was 92 and his blood pressure was 90/70. There was marked respiratory distress. The neck showed a marked subcutaneous emphysema. The trachea deviated to the right. There was subcutaneous emphysema over the left chest and in the left axilla. The right side of the chest was clear on percussion and ausculation. The left side was hyperresonant with an absence of breath sounds. The heart border could not be determined. The heart sounds were faint. The clinical impression on admission was a spontaneous pneumothorax of undetermined cause. X-ray studies revealed a left pneumothorax with subcutaneous emphysema on the left. He was seen by Dr. Thomas Kinsella in consultation. Dr. Kinsella's diagnosis was spontaneous rupture of the esophagus. A small amount of barium was given by mouth. X-rays showed the barium to pass into the left pleural cavity. A thoracotomy was done by Dr. Kinsella. A large amount of recently ingested food, fluid, and some barium was found in the left pleural cavity. Cultures from the fluid showed a variety of organisms with nonhemolytic streptococci predominating. A perforation was found on the posterior lateral wall of the esophagus just above the diaphragm. The tear in the esophagus was closed with silk sutures. Four drains were placed in the pleural cavity and continuous suction was applied. He was given large doses of penicillin and sufadiazine. His leukocyte count rose to 20,500 with 90 per cent neutrophiles. A large amount of fluid was aspirated from the left chest cavity by the suction apparatus. At times the suction was discontinued and penicillin introduced directly into the chest cavity for three hours at a time. Then the suction was continued for an hour. This regime was continued with considerable improvement in the patient's condition. On February 22, 1946, three days after admission, a chest film revealed complete re-expansion of the left lung with very little evidence of fluid present. On February 26, 1946, there was a mottled increase in density in the peripheral portion of the right lung field which had the appearance of pneumonia. He continued to show improvement until February 27 when he complained of sudden pain in the right chest. On February 28, he complained of a second attack of severe pain in the right chest with severe dyspnea. He died an hour later.

Dr. Robert Leighton: The postmortem examination showed the immediate cause of death to be a pulmonary embolus. The main branch of the right pulmonary artery was obstructed by a large antemortem blood clot. The right lung contained two small fresh hemorrhagic infarcts showing that he had minor embolic

---

From the Minneapolis General Hospital, A. J. Hertzog, M. D., Pathologist.

episodes prior to the fatal embolus. The source of the embolus was not demonstrated. The pelvic veins and upper femoral veins were free of blood clots. The embalming procedures prevents the pathologist from carrying out extensive dissection of the leg veins. The left lung showed only partial atelectasis and also showed a small infarct. The left pleural cavity showed a suppurative pleuritis but contained little fluid. The surface of the left lung was covered by old food particles.

The esophagus showed a linear ulcer on the posterior lateral aspect of the wall just above the cardia of the stomach. This tear measured 4 cm. in length and the outer surface was partially closed by sutures. The suture line had broken down and there was very little evidence of any healing. The surrounding mucosa of the esophagus showed evidence of an acute esophagitis. There was no evidence of any acute or chronic ulcers in the stomach or duodenum. Microscopic examination of the esophagus showed the wall to be necrotic and infiltrated with large numbers of neutrophiles. There was no evidence of malignancy.

Dr. Bronson: It is unfortunate that this man developed a fatal pulmonary embolus as his condition postoperatively was satisfactory and it appeared that he would have made a recovery from his operation.

Physician: Was there any foreign body responsible for the perforation?

Dr. Leighton: No. We have no reason to believe that any foreign body became lodged in the esophagus prior to its perforation.

Intern: Was there any ectopic gastric mucosa present in the esophagus in the region of the perforation?

Dr. Leighton: No. There was no evidence of any gastric mucosa present.

Dr. Hertzog: This is the third case that I have seen at autopsy of spontaneous perforation of the esophagus in the last three years. In the first case, I had difficulty convincing my colleagues that the perforation occurred prior to death and was not a postmortem perforation. Postmortem autolysis of the walls of the stomach is not uncommon and this sometimes may involve the wall of the lower esophagus. In postmortem autolysis of an organ, one does not get an acute ulcer with the walls infiltrated by an acute inflammatory exudate. In the past, many of these cases have probably been dismissed by the pathologist as examples of postmortem perforations. Two of these cases had definite x-ray evidence of esophageal perforation prior to death.

Spontaneous perforation of the esophagus is barely mentioned in the medical literature. Acute esophagitis is a fairly common finding at autopsy. It is more common in debilitated individuals. Regurgitation of gastric contents, vomiting and gastric intubation may all be etiological factors. The wall of the esophagus is thin. It is easy to see how in an occasional case of acute esophagitis an ulcer can occur with perforation. I think the part played by ectopic gastric mucosa in esophageal ulcers have been greatly overemphasized. I will briefly summarize the findings in the other two cases that I saw at autopsy. It is of interest that both of them had duodenal ulcers.

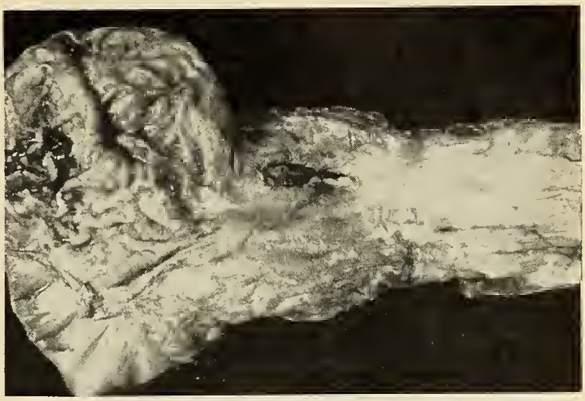

Fig. 1. Acute ulcerative esophagitis with perforation.

The first case was a seventy-three year old man who had enjoyed good health except for a chronic duodenal ulcer. On February 1, 1943, after his evening meal while sitting in a chair, he was seized with a severe epigastric pain. He was prostrated. His physician was called immediately. The clinical impression was a perforated peptic ulcer. He was admitted to St. Barnabas Hospital soon afterwards. X-rays of his chest and abdomen were taken. There was no evidence of any free air in his abdominal cavity. The chest film showed some consolidation at the base of both lungs. The abdomen was surgically explored. There was no evidence of any perforation of any intra-abdominal viscus. The patient's condition remained critical with signs of shock present. He expired approximately fifteen hours after the onset of his illness. Autopsy showed a perforation of the esophagus into the left pleural cavity with approximately 1500 c.c. of dark brown fluid that had the odor of gastric contents. The perforation of the esophagus occurred just above the diaphragm. Microscopically there was an acute ulcerative esophagitis. There was a chronic duodenal ulcer present.

The second case was a seventy-year-old-man who likewise had a history of a chronic duodenal ulcer. On November 27, 1944, he was seized with a sudden severe epigastric pain. He was admitted to St. Barnabas Hospital two hours after the onset of pain. Blood pressure was 90/50 and there were signs of shock. There was emphysema of the neck. X-rays showed fluid in his left pleural cavity with air throughout the mediastinum and soft tissues of the neck. He was treated for shock and received sulfa therapy and penicillin. Two hundred cubic centimeters of dark brown fluid was removed from the left pleural cavity. This showed a total acidity of 55 degrees. A tension pneumothorax developed. A second thoracentesis yielded 1,000 c.c. of fluid and 750 c.c. of air. The emphysema of his

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from April issue)

Early Conditions of Medical Practice

Physical conditions, of weather and roads, were those that for many years caused the medical practitioners of villages and rural communities the greatest labor and hazard in the conduct of medical practice. There is not a reminiscent comment that has come down from the earliest of pioneers or from their friends and families that does not touch particularly on the necessity for constant travel on horseback or in horse-drawn vehicles. Many stories stress the fact that the burden of opening a track, particularly on winter roads drifted full of snow, devolved on the doctors. The farmers, contrary to reasonable supposition, waited until the physicians, struggling through to their patients, had broken a trail. The unvarying theme is that of Dr. Oliver Wendell Holmes when he so well said of the general medical practitioner, "Half a dollar a visit—drive, drive, drive, all day; get up in the night and harness your own horse—drive again ten miles in a snow-storm; shake powders out of vial—drive back again, if you don't happen to be stuck in a drift; no home, no peace, no continuous meals, no unbroken sleep, no Sunday, no holiday, no social intercourse, but eternal jog, jog, jog in a sulky."

In 1858 J. W. Bishop, competent civil engineer, published his *History of Fillmore County,* mentioned earlier, "with an outline of her resources, advantages and the inducements she offers to those seeking homes in the West." (And these resources, advantages and inducements, he said, would with several minor modifications apply to the greater portion of Houston, Winona, Olmsted and Mower Counties and to Northern Iowa.) Among the advantages of the region he included the roads, for he optimistically set forth that "the wagon roads of the county have been but little worked as yet, but the face of the county and the nature of the soil are such, that good passable roads are found ready made, which, except in very wet weather, are smooth and hard, and may be travelled with heavy loads." Unhappily, although undobtedly this statement was true in all its parts, there was a great deal of "very wet weather."

In his memoirs Dr. Jacob Wright Magelssen, who came to Rushford in 1874 and spent the remainder of his long life in the village and community in active medical practice, gave a few lines to roads that must be a description to end descriptions:

> It would be hard to tell which was the worst season for a country doctor as far as the roads were concerned. In winter the wind sweeping over the prairies piled up drifts so impassable that I have sometimes tipped over four times in a half mile. Nothing for it then but to get out, shovel out the team, untangle them, and make another start. An hour of it would make me mad enough to shed tears of fury. But in the spring—Oh, those bottomless bogs that were called roads; those floods—freshets that carried away the flimsy little wooden

bridges; hill roads that were almost cut away. It was wonderful what tight places a pair of ponies could get out of. An automobile would have been of little use to me then.

There is a recurring note also of diversity of occupation among the early physicians, and the reason is found easily in the facts that money was scarce, population was sparse and settlements were miles apart.

Physicians in those years were glad to accept wood and farm produce in payment for their services and on occasion they even requested such recompense, sometimes by means of notices in the local newspapers. Probably every rural Middle Western medical practitioner in the fifties, sixties and early seventies and even later, turned his hand at one time or another to some occupation other than the practice of medicine. Many of these men owned and operated farms, sold trees, traded horses and cattle on a considerable scale, dealt in real estate, ran mills of various sorts or held paying offices or carried on several of these undertakings at once.

The practicing physicians of Fillmore County who owned and operated drugstores were many. And in mentioning druggists and drugstores, recognition should be given to the fact that in the early years many lay druggists were themselves medical advisors of no mean merit. Among them were men well known throughout the county. A few names that have been observed repeatedly are those of J. D. Eggleston, of Chatfield, Fillmore and Wykoff; John Iverson, Thomas Madland, Knud Olson and B. N. Ohlhouse, the last a manufacturer of "Nix Bitters," all of Rushford; John D. Dain, of Fillmore, who for a year or two was in partnership with Dr. J. W. Eighmy; J. C. Nelson, of Lanesboro, later a distinguished physician of Minnesota; J. L. Williams, of Spring Valley; G. Tayntor, of Chatfield, and James P. Tibbets and Albert Weiser, prominent citizens of Preston. Of those early drugstores the stock was as varied as the stock of drugstores now. There were, of course, in the newspapers countless advertisements, many of them by these stores, of patent medicines, among which preparations the "Oil of Life" apparently was a favorite. As the Editor of the *Chatfield Democrat,* in February, 1885, pronounced, there were "many comforting words to suffering humanity. Not an ill that us weak mortals are heir to but what has its specific remedy advertised to the skies with many promises of swift and certain cure. Were one-half of them able to do what is claimed, mankind would live forever, but we go on dying off at the rate of 90,000 every twenty-four hours just the same." Although some of the physicians-druggists announced that patent medicines were on sale, many of these practitioners compounded all of their own prescriptions.

If it was logical and practical for physicians to be druggists, it was even more so for them to serve as dentists, as most of them did, because it was a long time before the average village or town had a resident dentist. There were, however, traveling dentists, whose advertisements appeared regularly in the local newspapers in the early decades. Some of these men had their headquarters in villages of the county; two were Dr. T. E. Lyons, surgeon-dentist of Chatfield, and the well-known and well-loved Dr. H. W. Eldred, of Rushford. Others came on periodical visits into the county; among these were Dr. M. J. Stalker and, from Decorah, Iowa, Dr. T. A. Watson and Dr. W. D. Kellogg. Most of these dentists warned the public to beware of imposters and quacks "who are going around the county styling themselves 'dentists.' They will spoil your teeth, rob you of your money, and in the hour of need will be found wanting." Occasionally resident physicians of the villages in which the dentists visited would vouch through the press for the character and ability of these men and would advise the public to attend to their teeth, admonishing them that "a great deal of sickness, such as neuralgia, foul stomach, and so forth," arose from decaying teeth.

In a little later period, although resident general practitioners looked after such opthalmic conditions of disease as came their way and also fitted glasses, there were traveling oculists and opticians who visited communities periodically, as did the dentists, and admitted that whatever the trouble might be with the eyes of the citizens, they could cure it.

In view of the great versatality and adaptability of the pioneer physicians it is interesting that there was, even in the earliest decades that are considered here, some slight attempt at professional specialization among them. It has been noticeable, however, that the man who advertised as a specialist, in due course changed the wording of his announcements to make it clear that he was also a competent general practitioner of medicine and surgery. Probably, in order to make a living, he found it expedient to convince the public that the specialty was an added recommendation, not his whole equipment.

Beginning in the late sixties there became apparent a change in the wording of physicians' conventional professional cards as published in the local newspapers. As the announcements of itinerant practitioners of medicine and of traveling lecturers on physiology, anatomy, health and disease became more detailed and blatant, those of the permanent men became more conservative and the expression "resident physician" was used commonly. By the early eighties the custom of publishing professional cards of any type was falling into disuse. Ethically enough in those early decades, physicians called on editors of newspapers; and the editors, although their interpretations of medical news were sometimes startling and although their championship of individual physicians was not always desirable or helpful, played no small part in the dissemination of information as to the status of medicine locally in sundry aspects. There were gratuitous editorials, in one of which challenge was made to science, when a local physiomedical practitioner, about whom more will appear later, of brief residence, asserted that toads, frogs, snakes and lizards could maintain existence and could multiply in the stomach of man, "to vindicate" by showing how they could subsist and survive there. There were announcements that Dr. Smith or Brown or Jones had obtained genuine, reliable vaccine virus against smallpox which he was prepared to furnish to all families who wished to be protected against the disease. There was mention of performance of postmortem examinations by local physicians, with dramatic descriptions of the findings and, more helpful to the cause of medicine, praise of the families of the deceased persons for permitting the necropsies to be made. There were bland editorial notes such as this: "We are misinformed as to the medical attendance upon the Norwegian who cut his throat last week. Dr. Redmon instead of Dr. Case has the case in charge, under whose care the man is rapidly recovering and thinks he had rather live than die." And, "we were misinformed as to the present critical condition of———.*
His present condition gives every reason to hope for his speedy recovery from his serious burn. Dr. Ross deserves great praise for the skill and patience he has exhibited in treating the case, which has been all the more difficult from the aggravating scrofulous constitutional habit of the patient." There were comments that betrayed the existence of animus among medical brethren, particularly between those of different schools of thought. And, notably, it was the accepted practice for physicians, through the printed column, for reason of illness, departure, or plain need of cash, to invite their debtors to "come forward and pay up." Of interest also, if not of local significance, there began to appear in the county

---

*Here and elsewhere in this paper names of patients have been omitted by the writer.

newspapers, even in 1858, advertisements of medical journals; for instance, *The College Journal of Medical Science,* published in Cincinnati by Dr. C. H. Cleveland, and advertisements of medical colleges, one of which, in 1884, was the College of Physicians and Surgeons of Chicago.

In the earliest years of the county's settlement the chief occasions for services of physicians and surgeons were injuries from accidents. There were calamitous occurrences, tragic and lethal, in mills of various types. Mishaps occurred on farms, as follows, the instances taken at random from the many that were described in the local newspapers: A child was pecked viciously, to the point of death, by a large rooster; a boy chopping wood was injured on the back of his head by a heavy limb, "quite serious but not necessarily fatal"; a man stuck a five pound axe into his left instep; another broke his leg while taking horses to water; another was injured when a load of wood upset. Others were frightfully hurt and mutiliated when caught by the tumbling rod of a threshing machine; another was knocked on the head by a windlass; one man was hooked in the eye by a cow, "may lose eye." There were falls down cellars, off windmills, off wagons in runaways, and there were countless shooting accidents in hunting. There were obstetrical cases, although physicians were not always summoned in these, usually only in the event, as an early practitioner said, of " 'scare' or real difficulty." Seasonally, heatstroke and sunstroke and frostbite and freezing occurred, and there were cases of smallpox, of typhoid fever, of diphtheria, inflammatory rheumatism, consumption, inflammation of the bowels (in somewhat later years to be called "appendicitis"). Pneumonia, cancer of the stomach, and all other disorders known to man in the time and clime.

As nearly as can be determined, there was in Fillmore County prior to 1900, at widely separated times, only two hospitals, small private institutions. If there was other attempt at hospitalization of patients, it was informal and unorganized. There has been noted a time or two in newspapers of the late seventies brief reference to Dr. D. F. Powell's "Lanesboro Sanitarium." About 1896 Dr. George E. Campbell established in Wykoff a hospital which he owned and operated until he moved from the county in 1902.

In the pioneer years, and later, patients were treated for their ailments and were operated on, when emergency existed, sometimes in the physicians' offices but usually in their own homes. The kitchen table was the classic operating stand. Gradually physicians acquired improved equipment in the form of special tables and chairs to facilitate their work; occasional editorial announcement of such acquisition was made in the newspapers. Gradually also the local practitioners sought the aid of physicians and surgeons of larger towns within a radius of fifty miles who had wider experience than themselves. Incidents have been described in reminiscences and have been noted in news items of the eighties and nineties, when surgeons from Winona, La Crosse or Rochester, summoned in consultation, remained to perform surgical operations in homes, and when local physicians took their patients who required major surgical procedures to the hospitals in those larger towns. In the late nineties, as noted, and soon after the turn of the century men who had been recently graduated from the best medical schools of the Middle West began to enter practice in the villages of Fillmore County and to organize excellent private hospitals.

Organization of Medical Practice

With the close of the Civil War and the return to private practice of physicians and surgeons whose knowledge and experience had been increased and broadened by service to the wounded among the troops in the field and in military hospitals (since the Mexican War Military medical science had made great advances and military physicians and surgeons in the Civil War learned as well as served), there came an impetus to improvement in medical education and medical practice and to growth in solidarity among members of the profession. Packard, Walsh and others, have written fully about the development that made medical and surgical practice a thing quite apart from what it had been. Not all at once came the new appliances and apparatus, such as the clinical thermometer, the hypodermic syringe, the double stethoscope and the improved microscope, and their fullest use, nor the general employment of anesthetic agents, nor advances in diagnosis and the use of serums, antitoxins and vaccines, but the change had set in. Gradually, in therapeutics, calomel, opium, whiskey and the drastic purgatives yielded place to other preparations (in the eighties the coal tar products). The acceptance of the germ theory, and of antiseptics and asepsis in their turn, met opposition even in cities but especially in outlying districts and communities and particularly among the older physicians, who bitterly resented innovations in medical thought and practice, and in some few points these older men were right. "Although in time the electrical differentiation of organic disease and blood pressure apparatus brought great knowledge of patients and their ills, from the time when the tongue, the pulse, the hot or cool feeling of the patient, the taste of the urine and the general look of the stools" (Walsh) represented the data available for diagnosis, there nevertheless was much to be said for the unaided use of the special senses, and among the older practitioners were those who had wisdom not in books. They could read more than the facial expression of the patient, the appearance of the hands, the feeling of the skin and the odor in the sickroom than could some of their younger colleagues discern who had embraced all the new ancillary diagnostic aids. As one old gentleman has said, "Maybe they didn't know much by present-day standards, but anyway they could cure people."

In Fillmore County, as elsewhere, the new knowledge was felt. As time went on, the level of excellence in practice was raised, and there was presently a move toward medical education by outstanding men in the local profession who acted as preceptors to youths who aspired to medical practice. There were, of course, individual physicians who, although they favored education, as evidenced by their service on school boards, and had their points of excellence as practitioners, also had their flaws, even to slovenliness in professional conduct. One story that has come down through lay channels is about an early practitioner of the county who, after performing a postmortem examination in a rough workshop, nonchalantly filled the abdominal cavity of the cadaver with an old pair of overalls and some sawdust that he had scooped up from the floor. Of this same man an old resident of the county, a nonagenarian, has said, "Doc .... only saved one life as I know of. The druggist put up the wrong prescription, and lucky he noticed it soon enough and sent Doc out and Doc pumped out the man's stomach and saved his life. But all my folks doctored with him and they all died." Instances of professional inadequacy have been cited, among them that of the physician, newly graduated in the early eighties from a short course at a weak medical school, who was helpless and bewildered in the face of a little child's illness. The child died, to the unending heartache of the parents through long decades. The occurrence may have resulted in some good, because the father, a man of high intelligence and of professional training in another field, thereafter directed influence, which was not slight, toward the improvement of medical education, especially to the end of compulsory hospital internship before practitioners should be permitted to go into community practice. A few physicians have been recalled as drug addicts, others as habitual drinkers. One of the latter, well trained, brilliant and trusted in practice, was well aware of his shortcoming, and although when he was called in a case of serious illness he would respond promptly, he would insist on sleeping for an hour or two, on the floor if necessary, before examining the patient. And there were, around the beginning of the century, the two physicians, boon companions, who started on a hilly drive in poor weather into the country to fumigate a house in which there had been smallpox. Being a trifle overfortified, they forgot their fumigating equipment and remembered it only as they laboriously crested the last hill before their destination, whereupon they cheerfully agreed together that an old leather shoe that they discovered by the roadside, when cut up and burned in the infected room, would make as convincing a malodor as the proper agent.

A sign of the changing medical times was the occasional response of local practitioners to accounts in the public print of medical discoveries and marvelous surgical operations used in far parts of the country. These men arose, not in belligerence but in defense of the local profession and their attainments, and particularly, of the schools from which they came. When a story appeared of a wonderful repair of a broken and rebroken arm by means of removal of callus from the ends of the bones and the approximation of the ends and their fixation by the use of silver wire, by one Dr. Lane of San Francisco, Dr. Russell Lucretius Moore wrote the following letter to the editor of the *Preston Republican:*

Spring Valley, Minnesota,
December 3, 1872.

Editor, Fillmore County Republican:

Dear Sirs: In your issue of November 29 is an article described as "A wonder in surgery," by Dr. Lane, of San Francisco, not such a wonder after all to us boys who have attended "Old Rush" at Chicago, where most of us can recall as wonderful operations as this performed by our professors and teachers in Cook County Hospital and in our college clinics. In 1868 Powell and Boyue, at the hospital, performed the very counterpart of Lane's operation upon the ulna, one of the bones of the forearm, with a like good result. At the clinic of Dr. Powell's I saw him do a like job on the broken jaw of a woman, the fracture of which had failed to unite by other means. No use in going to San Francisco for wonders in surgery.

(To be Continued in the June issue)

President's Letter

NEED FOR MOVEMENT—"BACK TO SCIENTIFIC MEDICINE"

One of the most thought-provoking and action-inspiring letters which has come to my attention in many months or even years was a letter from Dr. E. L. Tuohy, President of your Association during 1945. Since it is of such vital importance to the whole profession, his permission to quote it in part, as follows, has graciously been given:

"(1) Look out for the sections of the state farthest from the central activities.

"(2) Stimulate the Councilors from these districts to become more energetic in returning the component medical societies to real medical enterprise.

"(3) Promote the growing centralization of medical service and interests in the hospitals. Extend the idea to the grouping of county society meetings about the 'hospital staff study of its own cases.'

"(4) Some day this could lead to the development of visiting staffs of pathologists, radiologists and likely other traveling specialists. Thus specialists could serve a large area rather than continuing the concentration of these dynamic teaching groups in the larger cities.

"(5) There is an abundance of medical brains in the rural districts. These brains are not focused upon that communal purpose without which individual doctors atrophy in this most dynamic period of medical development.

"In substance it is essential to get the profession back to scientific medicine. Private medicine will ultimately stand or fall on that basic issue."

Both of the first two items emphasize the necessity for as strong, cohesive, alert and well-informed organization in the hinterlands as in the larger urban centers. With access to every house in the land, the medical profession could be the most influential group in the country. As was brought out so emphatically at the last County Officers' meeting, public relations begin at home and nothing is so effective as "grass roots" letters to legislators. Yet, to perfect such an organization, it is imperative that every reputable physician in the state be a member and that each member not only be kept well informed but that he accept and discharge his full share of responsibility.

Most arresting, though, are the remaining suggestions. They point directly to the growing sphere of the hospital, and to the vital need for the continued high standard of medical care. To exploit rural hospitals as a medium for strengthening the organized medical profession, and also for raising the quality of rural medical care, is a truly colossal idea.

Effectiveness of such suggestions are seen in the enthusiastic reception of Dr. Tuohy's own clinical pathological conferences, and those at the University of Minnesota Medical School, Cornell University group, Cook County Hospital, the Mayo Clinic and innumerable others. Dr. Harvey Cushing's program of demanding that every intern write and present one scientific paper during his internship could easily be molded into the suggested program by requesting each hospital staff or society member to present one paper a year. More autopsies, clinic presentation of cases within the hospital, reports of unusual cases, group consultations, moving pictures of a clinical nature, and review of x-ray films offer limitless possibilities of good for both patients and physicians.

Up to the time of the war, University extension courses could be arranged in which members of the Medical School faculty would go to a hospital or medical society once a week. Even more recently suggestions for similar arrangements, as soon as present medical education pressures decrease, have been made within the Medical Foundation. And, undoubtedly, a multitude of other means of accomplishing the desired purpose can be arranged.

In brief, Dr. Tuohy's suggestions epitomize practical means of insuring the highest possible standard of medical care and also of keeping all physicians abreast of the remarkable progress in all branches of medicine. But, immediate action toward this desirable goal should be taken by each hospital staff, every physician, and officers of the component medical societies.

THE CHALLENGE OF GENERAL PRACTICE

THE general practitioner is the backbone of the medical profession, has been in the past and must continue to be in the future. He cares for an estimated 85 per cent of human ills, is capable of doing so and should continue to do so. For some 15 per cent of the ills, the specialist is essential and becomes more of a necessity as medical knowledge increases.

The specialist's work is often the more spectacular. He can do things that another man cannot. The possibility of his knowing all that is knowable in his specialty exists. Due to the rapid advance in medical knowledge, the general practitioner cannot possibly keep up with advances in all fields, but his field is much broader.

Until recent years, a doctor became a specialist by assisting a specialist, taking postgraduate training (often scanty in amount), or by simply declaring himself a specialist. Certification in the various specialties by National Boards is correcting the former unsatisfactory procedure, and certificates indicate that the holder has had certain minimal training which entitles him to rating as a specialist.

A specialist, as a rule, charges higher fees than the general practitioner, an incentive of course to invest more time and capital in postgraduate medical training.

Probably supply and demand have been the only law regulating the percentage of specialists in the past. We have the idea that today several factors have a tendency to urge a larger percentage of the profession into the specialties than is economically desirable.

In the first place, a framed certificate on the wall of the physician's office indicating certification in a certain specialty is flattering to the ego. Certification, too, makes the physician eligible to certain medical societies. Certification enables an individual to draw higher salaries in certain kinds of contract work. Certain hospital staffs are said to be limiting membership to licentiates of the specialties. If this procedure is extended, the general practitioner may find himself forced to turn over to a specialist a patient requiring hospital care. That time should not come, and the tendency to place the general practitioner at a disadvantage in regard to membership in certain medical societies and on hospital staffs is to be decried.

The hospital has a definite responsibility to the public as to the character of the medical work carried on in that hospital. It can and should make regulations requiring consultations for certain patients admitted by general practitioners and specialists when the illness is obviously beyond the ability of the general practitioner or specialist to treat. But regulations of hospital practice should not be to the detriment of the general practitioner.

Obviously, only areas of more concentrated population can support specialists. There is need for very few specialists of certain types in a whole state. The need, however, for the general practitioner in the city, as well as the sparsely populated districts, still exists. Many individuals prefer the services of a general practitioner, a physician with a broader general knowledge of medicine, for the 85 per cent of the ills to which flesh is heir. He can be relied upon to obtain consultation from the specialist when the need arises. Economically, this procedure is desirable.

There is no need for the general practitioner to feel any inferiority complex. There will always be a need for his services, both in city and country practice. There will never be a limit to the knowledge attainable by him. Occasions will often arise that will tax his ingenuity and skill—particularly in the country. At long last, a section for the general practitioner has been established by the American Medical Association which will add dignity to this group. Meetings of this section should prove popular.

Nothing should be done to discourage the general practitioner from remaining a general practitioner and the undergraduate from meeting the challenge of general practice.

DE KRUIF RECOMMENDS PROSTIGMIN

SOME favorable reports have appeared in medical literature regarding the use of prostigmin in cases of myasthenia gravis, poliomyelitis, stroke, arthritis, and spastic paralysis. Other reports have not been favorable. In other words, the value of the drug is still controversial. In this issue appears a report by John F. Pohl on his experiences with prostigmin in cerebral palsy. In brief, he could not determine that the drug was of any demonstrable value in this condition. Reports by physicians who are in a position to try out prostigmin on a number of patients suffering from these various neuromuscular conditions will eventually enable the profession to draw conclusions as to its value.

Prostigmin is a synthetic alkaloid belonging to the physostigmin group of drugs. Physostigmin, known as eserin, has been known and used for years by opthalmologists for its miotic effect and by surgeons for its stimulating effect on the intestines. Prostigmin was introduced in 1931 for its similar effect on the intestines, and four years later it was found to be effective in the symptomatic treatment of myasthenia gravis. Its symptomatic effect in this disease is said to be most dramatic. Theoretically, acetylcholine is supposed to be produced on muscle contraction at spinal motor-nerve endings and is neutralized by cholinesterase contained in the tissues. Prostigmin neutralizes the cholinesterase in the tissues and thus tends to increase the amount of acetylcholine at the motor-nerve endings, which is the site of the difficulty in myasthenia gravis. It has an anti-curare action, and atropine is its antidote. Just how prostigmin might be expected to ameliorate spastic symptoms in general is difficult to understand.

Although the value of prostigmin in the neuromuscular conditions mentioned is not established, it was the subject of an article entitled "Many Will Rise and Walk" by Paul DeKruif which appeared in the *Reader's Digest* for February. Those suffering from the aftermath of poliomyelitis, strokes, spastic paralysis, arthritis and other ills can hope for help from the use of prostigmin according to this well-known author and would-be medical authority.

This article on prostigmin is in keeping with several other articles on medical subjects which have appeared in the *Reader's Digest* in recent years. DeKruif's attitude of optimism in seizing reports of innovations in therapeutics which appear in medical literature and passing them on in a dramatic way to the public before the innovations have been firmly enough established to deserve general acceptance by the profession is misleading, to say the least. His advocacy of prostigmin for such a variety of complaints is in keeping with his article "Stamping Out Syphilis with One Day Treatment" which appeared in the December, 1943, issue of the *Reader's Digest*; with "Hope for Victims of Arthritis—Ertron" (November, 1943) ; and with "Can Man's Prime be Prolonged" (July, 1945). The fact that thousands of sufferers have their hopes falsely raised by such misleading articles does not seem to be sufficient for the owner of the *Reader's Digest,* DeWitt Wallace, to put a stop to their publication.

Those who had access to the November and December, 1945, numbers of *The New Yorker* know that Paul DeKruif is one of the numerous assistant editors in the employ of DeWitt Wallace, who owns the *Reader's Digest.* They understand, too, that only about 40 per cent of the articles that have appeared in the *Digest* in recent years are digests of articles which have appeared in other journals independently of the staff of the *Digest* editors. In other words, about 60 per cent of the articles that appear are original articles which have been written by the *Digest* editors and not published elsewhere (for instance DeKruif's) or have been "planted" in other journals gratis and abstracts run in an effort apparently to maintain the "digest" character of this phenomenal publication.

Overoptimism can be very misleading. While some of Paul DeKruif's articles have medical news value, too many fail to recognize that many a medical article which appears in print is but the personal experience of the author, and the ideas expressed must be confirmed or disproved before they can be generally accepted or rejected. Perhaps only a medically trained individual should attempt to evaluate medical literature for lay consumption.

A NEW ARMY MEDICAL LIBRARY BUILDING

Much as we are in favor of balancing the federal budget, certain expenditures on the part of the Federal government are "must" expenditures. We believe that an appropriation for the construction of a suitable building in Washington to house the Army Medical Library, formerly known as the Surgeon General's Library, is such a project.

Begun as a small collection of medical books in the office of the Surgeon General in Washington, great impetus was given in making the library the most complete medical library in the world by Dr. John Shaw Billings, who acted as librarian from 1865 to 1895. During this period, in 1887 to be exact, the present antiquated brick building which still houses the library was completed. The old structure constituted such a fire hazard that some of the more precious volumes were moved in 1942 to Cleveland, where space was provided in the Allen Memorial Medical Library for some 90,000 volumes.

In 1933 an effort to combine the Army Medical Library with the Library of Congress was prevented by the opposition of the Library of Congress, the Surgeon General and the medical profession. The proposal to locate the library at the Army Medical Center in Washington received considerable opposition a few years ago.

By 1941 Congress had appropriated $130,000 for the drawing of plans for a new Library and Museum to be located on Capitol Hill in Washington. Pearl Harbor put an end to all construction plans, although the war brought increased demands on the Library.

Some who live in the larger centers of population and have access to first class medical libraries do not realize the value of the Army Medical Library to the medical profession of the country. Long since, its volumes have been available to the profession of the country. The Library's ambition to possess all the medical books and journals published in this country, and most medical material published abroad, has well nigh been attained. The Library has afforded a center, ideal for medical research and for composing catalogues and abstracts, in addition to its being a lending library.

The late Dr. William H. Welch of Johns Hopkins University once said, "I have been asked on more than one occasion what have been the really great contributions to this country to medical knowledge. I have given the subject some thought and believe that four should be named: (1) the discovery of anesthesia; (2) the discovery of insect transmission of disease; (3) the development of the modern public health laboratory in all that the term implies; (4) the Army Medical Library and its Index-Catalogue. This Library and its catalogue are the most important of the four."

CYSTIC FIBROSIS OF THE PANCREAS

(Continued from Page 436)

torrhea, dwarfism, and chronic respiratory infection. Pathologically, it is characterized by obstruction of the ducts of the pancreas, salivary glands, and of the trachea and bronchi, with resulting secondary changes of a serious nature. Its etiology has not been proven.

The clinician would be well advised to investigate any case in which steatorrhea and respiratory symptoms are present with this diagnosis in mind. The roentgenologist can be of great assistance by recognizing the characteristic findings when these are present in the roentgenogram.

Minnesota State Medical Association
George Earl, M.D., Chairman

CONTRACTORS VOTE TO OPPOSE COMPULSORY HEALTH INSURANCE BILLS

The Associated General Contractors of Minnesota are among the organized groups that have gone on record as opposing any system of federally administered compulsory health insurance for this country.

Expressing their beliefs in a letter to Congressmen and Senators in Washington, the contractors voiced the opinion that extensive and even increasing governmental holds over the lives of this nation's citizens, whether it be manifested as interference with the construction industry or in taking over the medical and health professions, is "inimical to the nation's welfare, although in either case, it may be clothed with high sounding objectives."

A copy of this letter has been received in the office of the Minnesota State Medical Association, since it was in answer to a suggestion made by the State Office. The background of the letter may be summed up in this way:

Early in March there was sent out from the State Medical Association office an analysis of the Wagner-Murray-Dingell bills (S-1606 and HR 4730), the purpose of which was to bring together all of the reasons why the medical profession opposes legislation which has as its object the assumption by the federal government of the medical and health facilities of the nation and seeks to set up a system of compulsory health insurance, federally administered.

The analysis was done up in packet form and included material clipped from newspapers and from the *Congressional Record*, showing the concerted effort that has been and is being made to put a system of compulsory health insurance on the statute books.

Published material was also included which opposed such legislation, and a studied and critical statement was prepared in which the pros and cons of the question were carefully examined. It was suggested that readers evaluate for themselves the Wagner-Murray-Dingell proposals and that if they felt that the proposals were not beneficial to the nation, they should write their congressmen to that effect.

Here is the letter, signed by Mr. R. J. Hendershott, Manager of the Associated General Contractors of Minnesota, which was sent to Washington:

March 22, 1946

Dear Congressman ————:

Our attention has been called to S-1606 and HR 4730, the so-called Wagner-Murray-Dingell bills, proposing a general health and medical program on the part of the Federal government, and our Board of Directors at its meeting, March 13, 1946, voted to express its opposition to the proposed legislation.

This Association has been traditionally opposed to any legislation or practice for socializing industry or the professions. We feel that the proposed program set forth in the above-mentioned bills would be competitive with the type of service now rendered by the medical professions, and would, we fear, tend to destroy that much-to-be-desired mutual confidence that exists between patient and physician. It should be remembered that these professions have made and are making wonderful advances and nothing should be done to retard that steady progress.

We have always opposed construction practices of the Federal government or other public agencies, where such practices involved the taking over of contractor functions in the performance of construction work by day labor methods, namely, the hiring of workmen and the purchasing and use of equipment of governmental agencies.

We firmly believe that such a practice, either in the construction industry, or in the medical profession, is inimical to the nation's welfare, although in either case, it may be clothed with high sounding objectives. We also firmly believe that the time has arrived for a more rapid elimination of government wartime controls over industry and labor, and the elimination of many of the government controls which have grown up in recent years.

We hope that you will understand our position and express your opposition to the proposed legislation.

Very truly yours,
R. J. HENDERSHOTT, *Manager*

DOCTORS DISCUSS PREPAID MEDICAL SERVICE WITH LAY GROUP LEADERS

Getting at grass-roots sentiment on the subject of prepaid medical service, a special committee of Minnesota physicians sat down recently in St. Paul to talk the matter over freely and frankly with invited representatives of organized labor, civic and professional, as well as allied health groups.

There were representatives present from groups such as the American Federation of Labor and the Farmers Union who have gone officially on record in favor of the Wagner-Murray-Dingell Bill. Their spokesmen frankly stated that if adequate medical care can be provided for those in the low income groups at a state or local level, the demand for federal intervention would undoubtedly subside, but until that need is met by decisive action which embraces every individual, regardless of age or of economic standing, they felt there was no alternative except to seek federal support. A representative of the Minnesota Farm Bureau Federation countered that "there were so many in-laws of the federal government now that in addition to becoming very confusing it was getting distressingly burdensome; rural people wanted no more of it."

There was little doubt at the close of the meeting that when Minnesota launches its prepaid medical service program, there will be wholehearted co-operation from all groups in the state.

WORK OF MEDICAL UNIT OF WELFARE DIVISION SHOWN IN ANNUAL REPORT

During one month—the month of January, 1946—the Social Welfare division of the state Social Security department spent $20,715.33 for medical care and public health activities, according to figures which have been released by the division.

All medical activities of the division are handled by the Medical Service unit, which is headed by Edwin J. Simons, president of the Minnesota State Medical Association.

The Medical Service unit in its recently published annual report describes its work. There are, according to the report, four special activities of the unit—services to the deaf, maintenance of tuberculosis sanatoria, care of crippled children and services to public assistance recipients.

During the past year, says the unit report, aid to speech defectives and orthopedic-plastic crippled children has been on the increase to make up for the decrease in demands for care by the indigent and tuberculous cases.

Work of Unit Intensified

The work and efforts of the entire personnel of the Medical unit has been intensified, the report states, in meeting the demands required by medical advances and the problems created by the scarcity of professional services.

In addition to administration work in connection with medical care programs, the Medical Service unit provides consultation and advice in the handling of medical and dental problems in the aid programs. It is helped in this service by professional advisory committees, particularly in the development of fee schedules, statements of policy and similar problems.

It was decided that the Chief of the Medical unit would serve as medical consultant in the administration of the Barden-LaFollette rehabilitation program, working with the director of vocational rehabilitation of the Department of Education.

Crippled Children Services Subdivided

Four programs constitute the responsibility of the Medical unit in connection with services to crippled children. These are the orthopedic-plastic program, the rheumatic-cardiac or heart program, the cerebral palsy or spastic program and the program for speech defectives.

Under the orthopedic-plastic program, the unit provides four types of service: (1) hospitalization, (2) field clinics, (3) field nursing and (4) medical social work. In addition, a register is maintained of all known children under 21 years of age diagnosed as having orthopedic or plastic disabilities. As of July 1, 1945, there were 11,052 names of children on the register; of these, 2,444 were receiving one or more of the four services.

Hospitalization of crippled children is provided for those not eligible for treatment at Gillette State hospital, as non-residents living in Minnesota and Emergency Maternal and Infant Care patients. Last year 222 of these patients got 4,781 days of hospital care.

Eighteen field clinics were held during the fall of '44 and the spring of '45. Attendance showed an increase of from 1,311 for the previous year to 1,458 last year. There was an increase of from 240 to 274 new patients for the same period.

Rheumatic-Cardiac Program Expanded

Rheumatic-cardiac program facilities were greatly expanded. A contract for providing convalescent care for rheumatic fever patients was arranged with Sheltering Arms hospital in Minneapolis, and tutoring, planned play activities, occupational therapy and transportation between Sheltering Arms and Children's hospital for clinic services were added.

There were 446 visits by children to the clinic, with 120 cases admitted for clinic service. A total of 80 children suffering from rheumatic fever or heart ailments got 6,256 days of hospital, convalescent or foster home care.

Evaluation showed the results of the cerebral palsy or spastic program to be highly satisfactory, with seven children discharged and returned to the community. In the speech program an intensive speech retraining clinic for eight postoperative cleft palate cases was conducted at the University hospitals, sponsored by the Crippled Children services. It was considered highly successful. Eight new clinics throughout rural Minnesota were organized, bringing the total of speech field clinics to eleven. Through the speech program, a total of 131 speech defectives were provided training each month.

Deaf and Tuberculous Treated

Services for the deaf include interpreting, medical care, proper selection of hearing aids, testing, counselling and training for placement, obtaining social security records and helping in social adjustment.

At the beginning of the year, 233 cases were receiving service, with 116 cases closed during the year, 62 of which were considered rehabilitated. The year saw 146 new cases referred for service of which 38 are in supervised employment, 20 closed as rehabilitated and 15 closed for other reasons.

The section for tuberculosis sanatoria was occupied with efforts to make federal funds for tuberculosis control available through the U. S. Public Health service and the Minnesota State Department of Health.

Two projects are under way, the acquisition and use of two mobile x-ray units for diagnosis of tuberculosis and the establishment of a consultative committee of tuberculosis specialists to insure a state-wide, uniformly high standard of care for tuberculosis patients.

Counties Composing Sanatorium Districts Reshuffled

In spite of anticipated increases in the number of cases of tuberculosis in Minnesota, as a result of war, there actually has been an increase of vacant beds in the sanatoria of the state. This has led to redistricting of counties composing sanatorium districts in the southern part of the state and those served by the Minnesota State Sanatorium. In this redistricting project a subcommittee of the Tuberculosis committee of the Minnesota State Medical Association is serving in a consultative capacity.

Three principal developments have been accomplished at the Minnesota State Sanatorium. The first consists in adaptation of the x-ray equipment to use for therapy. This change is expected to increase the variety and standard of treatment provided patients in the institutions. Second, the laboratory was, during the past year, fully equipped for culturing of sputum specimens and other bacteriological work, which was necessary to relieve the Minnesota Department of Health of an excessive load of such work and to permit adequate examination at a minimum cost when the mobile unit assigned to the Sanatorium becomes operative. Third, a new dining room for patients was constructed and equipped, which development is in line with the program for patients in preparation for their discharge and safe return to society.

A total of 1,775 patients were admitted to all sanatoria in the state during 1944. In the same period, 1,860 patients were discharged, 20 per cent because of death. A total of 3,489 patients were under care during the year with the 1944 census showing 1,629 cases in all sanatoria.

Minnesota Academy of Medicine

Meeting of January 9, 1946

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 9, 1946. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 by the President, Dr. S. E. Sweitzer.

There were twenty-six members and one guest present.

Minutes of the December meeting were read and approved.

The following Memorial to Dr. H. A. H. Bouman was read by the Secretary for Dr. Hynes.

HERMAN A. H. BOUMAN

1870-1945

Dr. Herman A. H. Bouman, who was a member of the Academy from 1925 until his death following a heart attack on June 18, 1945, was born in Friesland on February 14, 1870. His early youth was spent in Germany where he received his elementary education. When he was twenty his family decided to come to America and settled in Clara City, Minnesota. Dr. Bouman attended the medical school of the University of Minnesota, graduating in 1897.

Between the time of his graduation and the year 1910 when he went abroad, Dr. Bouman taught anatomy and physical diagnosis at the University for four years, and later practiced medicine and surgery in New Richmond, for four years more. Then in 1910 and 1911 he studied in Switzerland under Dr. Kocher and from that time on was always intensely interested in diseases of the thyroid gland and very skillful in prescribing for such cases. In his leisure hours his great interest was the early history of medicine. He did much studying and writing on this subject, giving particular attention to the writings of Paracelsus. Dr. Bouman was a man of very set medical and sociological opinions which sometimes led to controversies. But in his home he was a very gracious host and loved nothing more than to surround himself with friends and spend the evening in genial talk.

He was a Fellow of the American College of Surgeons, a member of the State and Hennepin County Medical societies and of the Minnesota Academy of Medicine. He was also chairman of the board of directors of St. Andrew's Hospital and an Honorary Member of the Staff of Northwestern Hospital.

In 1903 Dr. Bouman married Kirsten Peterson, who died in 1940. In 1944 he married Matilda Menzel, who is left to mourn his loss, as is a daughter, Anchen, the wife of Dr. F. A. Zinter, of Minneapolis. Three brothers also survive him: the Rev. Henry Bouman of Minneapolis; Kles of Miles City, Montana; and Bernhard, of Great Neck, New York.

Dr. Lepak called to the attention of the Academy the fact that the organization had never been incorporated and also that the constitution, he felt, needed revision. He made a motion that the Academy be incorporated but before this should take place that the constitution be amended and that the president appoint a committee immediately to take such action. Motion seconded and carried. Dr. Sweitzer appointed as the members of such committee, Drs. La Vake, Camp, Schulze, and Dr. Lepak, Chairman.

The scientific program followed.

Dr. Schulze, Saint Paul, gave his address as Retiring President. Lantern slides were shown.

THE MANAGEMENT AND END RESULTS IN FORTY-FIVE CASES OF BREECH PRESENTATION IN PRIVATE PRACTICE

ALBERT G. SCHULZE, M.D.
Saint Paul, Minnesota

Breech presentations occur in from 2.8 to 4.8 per cent of all cases of labor according to various hospital and clinic reports. There is a maternal mortality ranging from 0 to .1 per cent and a fetal mortality ranging from 3.75 per cent to 10 per cent. One hospital reports eight infant deaths in twenty-seven breech deliveries (30 per cent) and nine deaths in thirty-six private cases (25 per cent).

Much as these figures vary, all obstetricians are agreed that full term or near full term single and uncomplicated pregnancies end as breech presentations in about 3 per cent of all cases and that there is a higher maternal morbidity and mortality and a higher fetal mortality associated with that type of presentation.

There may be several reasons why this small 3 per cent of babies in utero choose to assume the breech position, but eliminating such very apparent reasons as tumors of the uterus, placenta previa and twin pregnancies, the reasons which most authors give are expressed in such terms as, "deformity of the pelvis," "contracted pelvis," "a disproportion," "lack of cephalic accommodation," "a narrow pelvis," "lack of accommodation between head and pelvis." These may be satisfactory explanations in some cases but they leave much to be desired as an explanation for all cases.

There are definite advantages associated with a cephalic presentation which are entirely absent in a breech presentation. They are not as numerous as they are important.

There are several methods of doing pelvimetry but the best pelvimeter of all is the baby's head and the best type of pelvimetry is that known as the cephalopelvic type, or the ability to press the presenting head into the maternal pelvis by pressure over the fundus of the uterus. All other methods have but a relative value but this method has absolute value. There is also the advantage of the molding or shaping of the baby's head to the maternal pelvis brought about by the uterine contractions.

The serious disadvantage presented by a breech presentation concern themselves chiefly with the possible inability of the after-coming and unmolded fetal head to enter the maternal pelvis and the probability and almost certainty of deeper lacerations and the disaster which will be associated with each of these factors. There is also the increased probability of prolapse of the cord. The membranes are prone to rupture early in labor or even before labor has set in as happened in 50 per cent of the cases to be reported. The presenting breech is always out of the pelvis at the onset of labor; the pains are poor, the descent is slow and the dilatation of the cervix is time-consuming.

A frank breech has both its advantages and its disadvantages and the same can be said about a footling presentation.

Moreover, it is very evident that no obstetrician can acquire as much experience or attain as much composure in delivering breech presentations if they occur only to the extent of three per cent as he can in delivering babies in cephalic presentation when they occur to the extent of 97 per cent. This may account for some of the higher maternal and fetal mortality.

Because of this increased maternal and fetal morbidity and mortality associated with breech presentations over cephalic presentations for the reasons stated, Titus, DeLee, Stander, Shears, Randall and many others advocate and practice the conversions of a breech to a cephalic presentation in the latter months of pregnancy in order primarily to settle the question of a possible disproportion between the fetal head and the maternal pelvis.

This manual external change in fetal polarity is not a simple procedure. Polak states "external cephalic version is permissible if it can be done without violence; the indication for change is not sufficiently urgent if this obstetrical procedure is difficult."

It is best done at about the twenty-eighth week; the patient must be relaxed but not under an anesthetic as her co-operation is important. It often requires four hands and these must work in harmony and understanding with each other.

Nor is the attempt to do a cephalic version without danger. The membranes may be ruptured and cord complications may arise. DeLee states: "The operation of version may be fatal to the mother from rupture of the uterus, of the cervix or from abruptio placentae." Shears states; "It may cause fetal death by pressure on the cord or separation of the placenta." Perhaps these men have had these experiences.

Nor is external cephalic version always successful. Stander, while not fearing any of the complications which have been mentioned, finds the only drawback to be that the baby will not stay in its newly acquired position.

In the report by Patton and Mussey from the Mayo clinic in 1940 they speak of 10 per cent of successful versions leaving the reader to conclude that failure resulted in 90 per cent of trials or no attempt was made at all; very likely the latter explanation is the correct one. In a report of 100 breech cases by Gairdner and Jackson in 1941, they speak of 17 per cent of successful versions and 9 per cent of failures in sixty-four hospital cases. They favor cesarean section if versions fail and they resorted to this type of delivery in twenty-six of their 100 cases.

One cannot have much faith in cephalopelvic disproportion as being the etiologic factor in producing a breech presentation if one deliberately performs a cephalic version in order to test nature's accuracy. Why are there not more breeches associated with contracted or borderline pelves if a disproportion is a factor? One would expect a breech presentation in every such case.

Ryder reports his experiences in 258 breech presentations. He is a great avocate of external cephalic version as soon as a diagnosis of breech presentation is made, even though it be as early as the fifth month. He has developed a fine technique but admits 7.5 per cent of failures. In cases seen early in pregnancy he reports that 5.8 per cent underwent a spontaneous version. He admits that he had a greater number of cord complications and that the baby reverted to its original breech position in one-third of his cases; that he had to reconvert to a cephalic presentation two, three, four, five and six times in a various number of cases and in one patient he did it nine times and in another he did it thirteen times.

If one is successful in doing a cephalic version in these cases, he should then be able to determine the presence or absence of a cephalopelvic disproportion. If no disproportion exists and the baby does return to its original breech position, it should not be necessary to repeat the operation and to resort to it repeatedly is unnecessary obstetrical interference. If one fails in his attempt to do a cephalic version for any reason whatsoever, that failure should not in itself be interpreted to mean that a cesarean section is the proper and justified method of delivery. That is not a warranted conclusion.

The important and practical question in this problem of breech presentations is how is one going to deliver these cases at or near full term and which will go in labor as breech cases and which are uncomplicated by associated conditions which in themselves will dictate what will be the best type of delivery.

If a cephalopelvic disproportion is the reason for breech presentations, does it not seem illogical and a waste of time and courting trouble to flirt with the situation by doing a cephalic version with its recognized dangers and to force the baby in utero to assume a position from the uncertainty and dangers of which nature seems intent on saving it? Furthermore, prophylactic version during the latter months of pregnancy is successful only in certain cases so it cannot be more than a partial solution.

It has not been my policy to resort to prophylactic external version in these cases of breech presentation but to deliver them as breeches and it is the purpose of this presentation to report my results.

In going over my records I find forty-five cases of ull term or near full term single breech presentations, wo of which I delivered by cesarean section, leaving orty-three cases delivered as breeches.

BREECH CASES

Total number of cases	45
Delivered by section	2
Delivered as breeches	43

The diagnosis of presentation and position in the atter months of pregnancy is very important in every regnant woman and in these cases the diagnoses were s follows:

DIAGNOSIS OF POSITION

Correct diagnosis before labor	33	80%
Correct diagnosis in labor	3	
Error in diagnosis	6	
No diagnosis recorded	3	

The six cases recorded as errors in diagnosis may have een real errors and again the baby may have changed ts position between the time of examination and the late of delivery. This error in diagnosis was made at ne, three, five, nine, ten and eighteen days before labor et in. That the baby in the latter months of pregnancy nay assume any one of several positions is evidenced y the numerous times that Ryder repeated his external ersions and also by the fact that he reports that onehird of his 5.8 per cent of spontaneous versions took lace in the eighth and ninth months. In several of my ases the diagnosis of a head presentation has been made t more than one prenatal visit.

AGE OF PATIENTS

Up to 20 years	2
21 to 25 years	7
26 to 30 years	20
31 to 35 years	5
36 to 40 years	6
Over 40 years	3

PRIMIGRAVIDOUS PATIENTS

30 years	2	37 years	1
31 years	1	39 years	2
33 years	1	41 years	1

GRAVIDITY OF PATIENTS

Gravida 1	21	Gravida 4	1
Gravida 2	6	Gravida 5	1
Gravida 3	11	Gravida 6	3

TYPES OF BREECH PRESENTATIONS

Frank Breeches (15 Primiparas)	24
Single Footling	7
Double Footling	6
Compound presentations	4
No mention made	4

When it comes to the stage of the actual delivery of cases of breech presentations, Titus speaks of three schools of teaching and practice: those who resort to breech extraction at full dilatation; those who assist delivery; and those who do not interfere. I fail to see the reason or justification for breech extraction just because the cervix has reached the stage of full dilatation any more than the justification for forceps delivery in cephalic presentations when the cervix happens to be fully dilated. The stage of full dilatation is not always easy to determine and in a breech presentation it is most important to have full dilatation to insure safe passage for the unmolded after-coming head.

My efforts are rather along the line of watchful readiness to render proper assistance when the right time comes. Titus does not regard a breech presentation as being an abnormality as in many such cases delivery is spontaneous but perhaps with increase in the number of lacerations, maternal morbidity and fetal mortality. As long as satisfactory progress is being made I refrain from trying to improve matters or to hasten the time of delivery.

In this group of forty-three cases there were thirty-eight patients who delivered spontaneously or without assistance or any particular difficulty but in six cases assistance to the extent of breech extraction had to be resorted to.

Cases of Breech Extraction

Case 1.—Mrs. L. E. W., aged thirty-six, gravida 3, labor nine and three-quarters hours, footling presentation, full dilatation, artificial rupture of membranes, fetal heart tones very slow, non-pulsating engorged loop of cord, breech extraction, successful resuscitation; weight of baby 11 pounds.

Case 2.—Mrs. D. U. E., aged thirty-two, gravida 1, toxic in last month, hospitalized and labor induced, developed cardiac dilatation and pulmonary edema, fetal heart tones lost, breech extraction when cervix was fully dilated and condition permitted, frank breech, traction in groin; stillbirth.

Case 3.—Mrs. N. A. U., aged twenty-four, gravida 1, labor twenty-three hours, medical induction, membranes ruptured at full dilatation, brought down anterior leg, no pulsation in cord at umbilical stage, breech extraction; weight of baby 8 pounds.

Case 4.—Mrs. I. R. W., aged thirty-one, gravida 3, labor fifteen hours, membrane ruptured before onset of labor frank breech, no satisfactory progress, anterior foot brought down, posterior arm delivered, anterior arm turned to posterior position, easy extraction, no resuscitation necessary; weight of baby 10 pounds 5 ounces.

Case 5.—Mrs. M. U. R., aged thirty-three, gravida 1, in labor three days, dry labor, pains stopped, medical induction, inertia uteri, fetal heart tones irregular, sedation and oxygen, at full dilatation brought down anterior leg, extraction as fetal heart tones were not strong, baby ashen white but resuscitated; weight of baby 8 pounds.

Case 6.—Mrs. B. U. T., aged twenty-nine, gravida 1, membrane spontaneously ruptured six hours before labor set in fifteen days before calculated date, hydramnios, primary inertia uteri, labor two and one-half days, poor response to uterine stimulation, slow dilatation, perineum ironed out, footling presentation, breech extraction, forceps for aftercoming head, third degree laceration; weight of baby 7 pounds 5 ounces.

In all other cases the Mauriceau method was resorted to in delivering the after-coming head, one knee of the obstetrician being placed on the floor.

There was one instance of each of the following cord involvements, none serious enough to be regarded as a cord complication:

Loop of cord prolapsed to the perineum,
Non-pulsating cord and extraction,
One coil about the neck,
Coil about neck and leg,
Two coils about the neck,

Two coils about neck and a true knot,
Three coils about the neck,
Two coils about the body.

It is interesting to speculate as to what might have been the fate of the baby if a cephalic version had been done or even attempted. It is at least a fair question.

In at least one hospital there is a rule in the obstetrical department that every breech delivery must be preceded by an episiotomy. I did not do an episiotomy in every case and perhaps should have done it oftener. I have learned to regard it as a very important part of every breech delivery.

EPISIOTOMIES AND LACERATIONS

No episiotomy and no laceration	15	(2 primiparas)
Episiotomy only	14	(9 primiparas)
Episiotomy and laceration	5	
No episiotomy but laceration	9	

In this group of cases, one patient died of a non-convulsive toxemia about six hours after delivery. It was the only maternal death and the breech presentation was not a factor. This makes a corrected maternal mortality of zero. Two babies were lost but neither death was due to the breech position. This makes a corrected fetal mortality of zero.

The question of maternal morbidity was approached from two angles. Taking the accepted criterion of 100.4 degrees or above on any two postpartum days as significant fever, there were only two patients who would be so classified. There were three patients who had this elevation of temperature on only one day. Two charts could not be located in the hospital record room.

The second approach to the question of morbidity was the pelvic condition of the patient at her final examination at six or eight weeks postpartum. Eight patients did not report. Without going too much into detail, the impression is gained that there is nothing unusually pathologic in these cases. The majority had normal pelves and no complaints. Perhaps the uterus was retroverted in a larger number than one usually finds but the record shows that this condition was present before or early in pregnancy in several of the cases. There was only one patient whose condition was not satisfactory. She had sustained a third degree laceration due, I feel, to a too rapid delivery of the head and she did not regain the fullest control of the sphincter muscle.

In this presentation it is not my desire to settle the question of how best to deliver cases of breech presentation at full or near full term. I am only giving my experiences. It includes forty-three cases; women of all ages and all gravidity; breeches of all types. Some women had episiotomies, some did not; some had lacerations and some did not; some had both. In six cases breech extraction had to be resorted to. There resulted a corrected maternal mortality and a fetal mortality of zero and only two cases of maternal morbidity. In all cases breeches were delivered as such, no attempt at external cephalic version having been made.

After reviewing these forty-five cases of full term breech presentations and noting the opinions and experiences of others, several obstetrical impressions are obtained which might be presented as conclusions, namely:

1. Cephalopelvic disproportion is not a satisfactory explanation as to why the baby in utero takes the breech position. There must be other reasons.
2. The dangers and the uncertainties of a prophylactic external version seem to be no less than the complications of a breech delivery.
3. When following an external cephalic version it is found that no disproportion exists, it would seem unnecessary to repeat the maneuver if the baby returns to its breech position.
4. In a multiparous woman who has had uncomplicated cephalic deliveries, it should not be necessary to do an external cephalic version if, in her next pregnancy, she has a breech presentation.
5. Inability to do an external cephalic version should not in itself be interpreted to mean that a cesarean section is the proper method of delivery. That is not a warranted conclusion.
6. Cesarean section in 26 per cent of breech cases when external cephalic version fails is an astoundingly high per centage and perhaps not fully justified.
7. An episiotomy should precede every full term breech delivery.

Discussion

Dr. J. C. Litzenberg, Minneapolis: I would like to compliment Dr. Schulze on his handling of these breech cases with a corrected mortality of zero for the mother and child. He had no reason for being embarrassed by my presence. My results are certainly no better and I doubt if they are as good and his conservative attitude is certainly to be commended. I have disagreed with him on one point in the past and that is doing external version. He was in my department during our existence of teaching together and he will remember that I always taught that an external version was indicated only if it was easy. If it is easy, it is all right but if it is difficult it is too dangerous. I want to congratulate Dr. Schulze on his conduct of breech presentation and his results and certainly his results justify his conservative attitude. Most babies should be delivered as breeches. During my stay in Vienna there was a period during which no breech was given assistance. They modified that later in certain cases, just as Dr. Schulze has done.

Dr. R. T. La Vake, Minneapolis. This is an excellent and timely paper. Dr. Schulze's experience with external version has been similar to mine, and I think to that of most men. External version has its definite dangers as outlined by the essayist and Dr. Litzenberg.

Cesarean section in breech presentation should require the same indications as are required in vertex presentation. Where a slight doubt exists, in the case of a young woman, it is my opinion that her whole future is better served by a trial of labor and not by an elective cesarean, which may unnecessarily jeopardize her future obstetrical possibilities by a scar in the uterus. This was Dr. Cragin's philosophy and my experience and observations have corroborated its wisdom.

Men will not fear breech presentation if they follow Dr. Schulze's rule of nonintervention except for definite valid indications on the part of mother and child, after the cervix is thoroughly dilated: if they have aftercoming head forceps at hand, and if they have trained assistants. Of all operations in obstetrics, breech delivery is the operation whose results are most influenced by the character of the available assistants. For twenty years, two of us have assisted each other in every breech delivery and our results have approximated our vertex results. The importance of trained assistants cannot be too greatly stressed.

Dr. John A. Haugen, Minneapolis (by invitation): I would like to congratulate Dr. Schulze on his fine presentation. His summaries emphasize the value of careful determination of position and presentation at the prenatal visits. His policy of non-interference" as long as there is progress must have a great deal to do with the splendid results obtained.

The meeting adjourned.

A. E. Cardle, M.D., *Secretary*

MALARIA IN MINNESOTA

(Continued from Page 428)

after transfusion with blood from an ex-serviceman or other person who has been in a malarious area, the patient manifests chills and fever, thick smears should immediately be examined for the presence of plasmodia.

As a result of returning personnel, infected with plasmodia, we may expect to see a few satellite cases of malaria in Minnesota. An attempt should be made to find the person acting as the reservoir, who will in all probability reside near by; anopheline mosquitoes do not fly far for their blood meal. Programs directed toward eliminating anopheline mosquitoes in the state will have their advocates, but in Minnesota, the benefits derived will probably not offset the cost. Malaria now, as in the past, will burn itself out.

PERFORATION OF ESOPHAGUS

(Continued from Page 443)

neck increased. The possibility of a ruptured esophageal carcinoma was considered. His temperature became elevated and he expired on the third day after admission. An autopsy showed a perforation of the esophagus into the left pleural cavity. There was a linear ulceration of the esophagus just above the diaphragm (Fig. 1). The surrounding esophagus in this region showed an acute esophagitis. Microscopically the wall was necrotic and infiltrated with an acute inflammatory exudate. There was no evidence of any neoplasm or ectopic gastric mucosa. There was also a chronic duodenal ulcer.

In summary, all three of these patients were old men. Two of them had chronic duodenal ulcers. The third frequently took bicarbonate of soda for heartburns. I think that we can conclude that all three of them suffered from an acute esophagitis prior to the perforation of the esophagus. Subcutaneous emphysema was present in two of the cases. This finding together with the x-ray evidence of fluid in one pleural cavity should establish the diagnosis. We have good reason to believe that the third patient would have recovered following surgery had he not developed a fatal pulmonary embolus.

Colonel Francis R. Dieuaide, up to recently Chief of the Tropical Disease Treatment Branch of the Surgeon General's Office, has been named Scientific Director of the Life Insurance Medical Research Fund, it was announced today by M. Albert Linton, chairman of the Fund.

Dr. Dieuaide, who received the Legion of Merit for his supervision of the treatment of malaria and other tropical diseases in the Army, is now on terminal leave. He will assume his duties with the Life Insurance Fund on April 1. Before going into the Medical Corps in 1943, Dr. Dieuaide was Clinical Professor of Medicine at the Harvard Medical School, a post which he is resigning.

The Life Insurance Medical Research Fund was established last year to make grants to universities and medical schools for research on diseases of the heart and related diseases. The fund plans to make grants of more than $3,000,000 for this purpose over the next five years. A total of 147 life insurance companies in this country and Canada are supporting the fund.

Minnesota State Medical Association

Ninety-Third Annual Session

Saint Paul Municipal Auditorium, Saint Paul, Minnesota

May 20, 21 and 22, 1946

ANNOUNCEMENTS

Scientific Cinema—Please note that scientific motion pictures will be shown in the West Arena before each morning and afternoon session, at the conclusion of Monday and Tuesday sessions and at each intermission. Provided through the courtesy of the Medical Film Guild, these films present refresher courses in fundamental medical problems in a wide range of subjects.

Luncheons—Twenty Round Table Discussion Luncheons have been arranged for Tuesday and Wednesday, May 21 and 22, at the Lowry and Saint Paul Hotels. Tickets must be purchased in advance for these luncheons. Lists of subjects and leaders are printed in this program and on the reservation cards mailed with the program. Attendance at each luncheon is limited to thirty, and late comers will be accommodated according to their choice if limits have not already been reached. Tickets $1.25.

Annual Banquet—The annual banquet for members, guests and their wives will be held at the Hotel Saint Paul, Tuesday evening, May 21, at 7 p.m. James Lewis Morrill, LL.D., President of the University of Minnesota, and Edwin J. Simons, President of the Minnesota State Medical Association, will be banquet speakers. Tickets $2.50.

Guest Speakers—We are indebted to the following societies for guest speakers at this meeting:

The Northwestern Pediatrics Society—Speaker, Henry G. Poncher, Professor of Pediatrics, University of Illinois, Chicago, Ill.

The Minnesota Radiological Society—Speaker, Byrl R. Kirklin, Section on Roentgenology, Mayo Clinic, Rochester, who will deliver the annual *Russell D. Carman Memorial Lecture* in Radiology.

The Northern Minnesota Medical Association—Speaker, M. Edward Davis, Department of Obstetrics and Gynecology, Chicago Lying-in Hospital of the University of Chicago, Chicago, Illinois.

The American College of Chest Physicians—Speaker, L. L. Sanford, Muirdale Sanatorium, Milwaukee, Wisconsin.

Saint Paul Surgical Society—Speaker, George M. Curtis, Professor of Surgery, Ohio State University, Columbus, Ohio.

Academy of Ophthalmology and Otolaryngology—Speaker, Joseph A. Sullivan, Toronto, Ontario, Canada, and Elmer A. Vorisek, Chicago, Illinois.

Other guest speakers at this meeting:

F. H. Arestad, Council on Medical Education and Hospitals, American Medical Association, Chicago.

Mr. Graham L. Davis, Hospital Director, W. K. Kellogg Foundation, Battle Creek, Michigan.

Newell C. Gilbert, Professor of Medicine, School of Medicine, University of Chicago, Chicago, Illinois.

Mr. James A. Hamilton, Hospital Consultant, Yale University, New Haven, Connecticut.

Mr. Gottlieb R. Magney, architect, Minneapolis, Minnesota.

William D. Stovall, Director, State Laboratory of Hygiene, Service Memorial Institute, Madison, Wisconsin.

Medical Women's Luncheon and Dinner—The American Medical Women's Association, Minnesota Branch, will hold a luncheon meeting at the Young Women's Christian Association, situated on Fifth Street across from the Auditorium, Monday, May 20, at 12:15 p.m. Monday evening there will be a dinner at the Women's City Club, 305 St. Peter Street. All women physicians are invited to both of these meetings. Make reservations in advance through Nellie N. Barsness, 540 Lowry Medical Arts Building, Saint Paul 2. Tickets $1.50.

Medal—The Southern Minnesota Medical Association will present its annual medal for the best scientific exhibit presented by an individual physician at this meeting. Presentation will be made at the banquet, Tuesday evening, May 21, at Hotel Saint Paul.

Fifty Club—This year's candidates for election to Minnesota's "Fifty Club" will be honor guests of the Association at the 93rd Annual Banquet to be held Tuesday, May 21, at 7 p.m. at Hotel Saint Paul. Presentation of lapel buttons and certificates to candidates who have practiced medicine for 50 years in Minnesota will be a feature of the banquet program.

Technical Exhibits—This year's exhibit will be one of the largest in the Association's history. On display in the St. Paul Auditorium Arena, the exhibit plays an important part in the interest and value of every state meeting. The revenue from sale of exhibit space makes possible the high quality of scientific program and events characteristic of Minnesota meetings. Every convention visitor should make a point of visiting the technical exhibits.

Woman's Auxiliary—Wives of physicians attending the meeting may register and secure programs at the Women's Headquarters in Hotel Lowry. There tickets will be available for the various social functions and meetings. All visiting women are cordially invited to attend the special events, arranged by hostesses of the Ramsey County Auxiliary.

Golf—The annual Golf Tournament of the Minnesota State Medical Association will be held Sunday, May 19, at the White Bear Yacht Club. All medical golfers are urged to enter and compete for the attractive prizes that have been donated for winners.

Medical Art Exhibit—A collection of 300 outstanding original oils, water colors and drawings, the work of 17 foremost American artists, from the famed Abbott Collections of Army and Navy Medical Paintings, will be exhibited in the Auditorium Arena. The paintings present vividly an authentic record of medicine's part in the winning of World War II, showing scenes from the home front and from the battlefields. The Association is indebted to Abbott Laboratories, which commissioned the artists, for lending the exhibit to the Association for showing at this time.

Saint Paul Surgical Society—The Society is sponsoring a special dinner meeting Monday evening, May 20, to which ALL physicians are cordially invited. Guest speaker is the noted surgeon, George Morris Curtis, Professor of Surgery at Ohio State University, who will speak on the subject "Iodine and the Thyroid Gland." A cocktail hour at 6 p.m., sponsored jointly by the Surgical Society and the Ramsey County Medical Society, to be held in the Windsor Room of Hotel Saint Paul, will precede the dinner, which is being served in the Continental Room.

Minnesota Academy of Ophthalmology and Otolaryngology—The Academy will be host to its members at golf on the afternoon of Monday, May 20, and will hold its annual dinner meeting at the Minnesota club that evening. Guest speaker will be Joseph A. Sullivan, Toronto, Canada, who will speak on "The Symptom Complex of Labyrinthine Vertigo."

SPECIAL SESSIONS

In addition to the general sessions to be held Monday, Tuesday and Wednesday in the Auditorium theater, there will be three special sessions to be held in the morning of each of the three convention days and a special conference, set for the afternoon of the third day.

Monday, May 20, 9 a.m.—The Minnesota Academy of Ophthalmology and Otolaryngology will sponsor a special program in Stem Hall at the St. Paul Auditorium on Monday at 9 a.m. This program is open to all convention visitors. For details, see program listings.

Tuesday, May 21, 9 a.m.—A special program on orthopedic and fracture surgery has been arranged for Tuesday at 9 a.m. This program will be given in Stem Hall and will recess from 10:15 a.m. to 11 a.m. at the same time as the general session, so that those who attend may visit exhibits, demonstrations and the Scientific Cinema. All convention visitors are welcome to attend this session. Details are given with the program listings.

Wednesday, May 22, 9 a.m.—The American College of Chest Physicians is sponsoring a session on chest diseases, Wednesday at 9 a.m. in Stem Hall. This session will recess also from 10:15 to 11 a.m. Convention visitors may attend. For details, see the program listings.

Planning the Modern Hospital—A special conference on this very timely subject will conclude the program Wednesday, May 22, from 2 to 5 p.m. Nationally known authorities will be present to discuss various important phases of the local and national problem. Members of the Minnesota Hospital Association and allied organizations, city planning boards, social welfare workers, school authorities and representatives from various lay, professional, civic and organized labor groups will be invited to attend.

DEMONSTRATIONS

A program of demonstrations, to be held in Booths D-1 and D-2 in the Auditorium Arena, has been arranged for each intermission period and immediately preceding each general session on Monday, Tuesday and Wednesday, May 20, 21 and 22.

D-1 Epidemic Ringworm
Minnesota State Department of Health

D-2 Blood, Blood Substitutes and Venipuncture
Committee on First Aid and Red Cross
Minnesota State Medical Association

In addition, on Tuesday, May 21, M. Edward Davis of Chicago will give two obstetrical demonstrations, the first at 12:15 p.m. at a Round Table Luncheon at Hotel Saint Paul, the second, also at Hotel Saint Paul, at 5 p.m. in the Windsor Room.

SCIENTIFIC PROGRAM

Monday, May 20

Section I—General Session

A.M.

8:00 Scientific Cinema................West Arena
Visit Scientific and Technical Exhibits....Arena

8:30 Demonstrations—Booths D-1 and D-2

9:00 **Jaundice**................Auditorium Theater
- Diagnosis and Medical Management—Frederick W. Hoffbauer, University Hospitals, Minneapolis
- Surgical Treatment of Obstructive Lesions at the Head of the Pancreas—John M. Waugh, Rochester

9:40 **Brucellosis**
- Clinical Aspects—Wendell H. Hall, University Hospitals, Minneapolis
- Methods of Control—Willard L. Boyd, D.V.M., Division of Veterinary Medicine, University of Minnesota Farm School

10:15 *Intermission*

Scientific Cinema ....West Arena
Visit Scientific and Technical Exhibits....Arena
Demonstrations—Booths D-1 and D-2

11:00 **Coronary Heart Disease**
- Emergency Treatment—Royal V. Sherman, Red Wing
- Prognosis and Life Adaptation—Arlie R. Barnes, Rochester
- Coronary Heart Disease—The Occupational Disease of Doctors—Newell C. Gilbert, Professor of Medicine, School of Medicine, University of Chicago

Afternoon

P.M.

1:00 Scientific Cinema................West Arena
Visit Scientific and Technical Exhibits..Arena

1:30 Demonstrations—Booths D-1 and D-2

2:00 **Military Disease in Civilian Life**
- Tropical Diseases—Thomas B. Magath, Rochester
- Malaria—Donald McCarthy, Minneapolis
- The Bacillary Dysenteries—Joseph F. Borg, Saint Paul
- Preventive Procedures and Practical Suggestions—Gaylord W. Anderson, University of Minnesota

3:15 *Intermission*

Scientific Cinema................West Arena
Visit Scientific and Technical Exhibits..Arena
Demonstrations—Booths D-1 and D-2

4:00 Russell D. Carman Memorial Lecture
Auditorium Theater
- The Outlook for Postwar Medicine as Seen by a Radiologist—Byrl R. Kirklin, Rochester

5:00 Scientific Cinema...................West Arena
Visit Scientific and Technical Exhibits.....Arena
Demonstrations—Booths D-1 and D-2

6:30 **Saint Paul Surgical Society**
(Listed under Section II, Special Session)

Monday, May 20

Section II—Special Session

A.M.

9:00 **Minnesota Academy of Ophthalmology and Otolaryngology** ....Stem Hall

Evaluation of the Newer Therapeutic Agents in Ophthalmology—Elmer Vorisek, Chicago, Illinois

10:00 Pentothal Sodium Anaesthesia in Cataract Surgery—James S. Reynolds, Minneapolis

10:20 Some Experiences in the Treatment of Chronic Mastoid Diseases—Eugene McElmeel, Senior Resident in Otolaryngology at University of Minnesota

10:35 Case Studies—Wilfred Bushard, Senior Resident in Ophthalmology at University of Minnesota

11:00 The Effect of Flight Upon the Ear—Joseph A. Sullivan, Toronto, Canada

P.M.

6:30 **Saint Paul Surgical Society**..Hotel Saint Paul

Iodine and the Thyroid Gland—George Morris Curtis, Professor of Surgery, Ohio State University

A special dinner meeting will be held at the Hotel Saint Paul, sponsored jointly by the Saint Paul Surgical Society and the Ramsey County Medical Society. The guest speaker, George Morris Curtis, Professor of Surgery at Ohio State University, will discuss the newer factors that are being added to the iodine story and the clinical applications of the scientific findings. Dr. Curtis is an outstanding surgeon who has done extensive research work in connection with the thyroid gland.

Tuesday, May 21

Section I—General Session

A.M.

8:00 Scientific Cinema..................West Arena

Visit Scientific and Technical Exhibits....Arena

8:30 Demonstrations—Booths D-1 and D-2

9:00 **Thrombophlebitis and Postoperative Emboli** Auditorium Theater

Surgical Treatment of Thrombophlebitis—John R. Paine, University of Minnesota

Dicumarol and Heparin—Nelson W. Barker, Rochester

9:45 **Surgical Treatment of Bronchiectasis**

Thomas J. Kinsella, Minneapolis

10:15 *Intermission*

Scientific Cinema..................West Arena

Visit Scientific and Technical Exhibits....Arena

Demonstrations—Booths D-1 and D-2

11:00 **Sulfonamides and Antibiotics in General Practice**

Walter S. Neff, Virginia

Penicillin

John F. Briggs, Saint Paul

Streptomycin

Wallace E. Herrell, Rochester

P.M.

12:15 **Round Table Luncheons**......Saint Paul and Lowry Hotels

Afternoon

1:00 Scientific Cinema..................West Arena

Visit Scientific and Technical Exhibits....Arena

1:30 Demonstrations—Booths D-1 and D-2

2:00 **Obstetrics for the General Practitioner**

Treatment of Obstetrical Shock—Russell J. Moe, Duluth

Rh Factor and Blood Transfusions—Rudolph W. Koucky, Minneapolis

Modern Management of the Third Stage of Labor and the Prevention of Postpartem Hemorrhage—M. Edward Davis, Department of Obstetrics and Gynecology, Chicago Lying-in Hospital

3:15 *Intermission*

Scientific Cinema..................West Arena

Visit Scientific and Technical Exhibits....Arena

4:00 **Pediatric Hematology**

Henry G. Poncher, Professor of Pediatrics, University of Illinois, Chicago

5:00 Scientific Cinema..................West Arena

Visit Scientific and Technical Exhibits....Arena

Demonstrations—Booths D-1 and D-2

Obstetrical Demonstration........Windsor Room Hotel Saint Paul

M. Edward Davis, Department of Obstetrics and Gynecology, Chicago Lying-in Hospital

7:00 Annual Banquet (Listed under Section II, Special Session)

Tuesday, May 21

Section II—Special Session

A.M.

9:00 **Orthopedic and Fracture Surgery**..Stem Hall

Myron O. Henry, Minneapolis, Chairman

Newer Methods Developed in the Treatment of Chronic Infections with Special Reference to the Treatment of Osteomyelitis—Edward T. Evans, Minneapolis

Dysplasias of the Hip Joint—Vernon L. Hart, Minneapolis

Fracture—Dislocations of the Cervical Spine S. D. Houkom, Duluth

10:15 *Intermission*

Scientific Cinema..................West Arena

Visit Scientific and Technical Exhibits....Arena

Demonstrations—Booths D-1 and D-2

11:00 **Orthopedic and Fracture Surgery,** Continued ....Stem Hall

Fractures of the Elbow Joint in Children—D. L. McCain, St. Paul

Plantar Neuromas, Morton's Toe—W. H. Bickel, Rochester

P.M.

E. W. Hansen, M.D. (1947)	Minneapolis

Alternates

J. C. Hultkrans, M.D. (1946)	Minneapolis
W. L. Burnap, M.D. (1946)	Fergus Falls
George Earl, M.D. (1947)	St. Paul
W. W. Will, M.D. (1947)	Bertha

SCIENTIFIC COMMITTEES

COMMITTEE ON SCIENTIFIC ASSEMBLY

Edwin J. Simons, M.D., General Chairman	Swanville
E. L. Tuohy, M.D.	Duluth
R. R. Rosell	Saint Paul

Section on Medicine

C. B. Drake, M.D.	Saint Paul
W. W. Spink, M.D.	Minneapolis

Section on Surgery

O. T. Clagett, M.D.	Rochester
O. J. Campbell, M.D.	Minneapolis

Section on Specialties

C. L. Oppegaard, M.D.	Crookston
Paul F. Dwan, M.D.	Minneapolis

Local Arrangements

A. P. Gruenhagen, M.D.	Saint Paul

COMMITTEE ON CANCER*

A. H. Wells, M.D. (1947)	Duluth
Charles Bolsta, M.D. (1946)	Ortonville
Herbert Boysen, M.D. (1946)	Madelia
E. C. Hartley, M.D., (1946)	Saint Paul
James A. Johnson, M.D. (1948)	Minneapolis
R. W. Koucky, M.D. (1946)	Minneapols
F. H. Magney, M.D. (1948)	Duluth
Martin Nordland, M.D. (1948)	Minneapolis
W. T. Peyton, M.D. (1947)	University
W. C. McCarty, M.D. (Sr.) (1947) (ex officio)	Rochester
W. A. O'Brien, M.D. (1947) (ex officio)	University

COMMITTEE ON FRACTURES

V. P. Hauser, M.D., General Chairman	Saint Paul

Executive Committee on Fractures

V. P. Hauser, M.D.	Saint Paul
N. H. Baker, M.D.	Fergus Falls

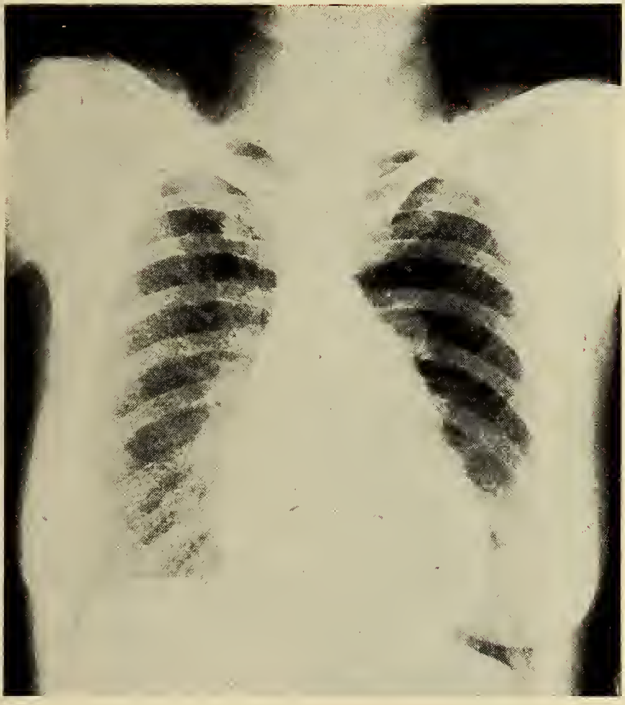
congestive heart failure



The de-edematizing action of Searle Aminophyllin decreases the cardiac burden, permitting the heart muscle to function more efficiently.

Searle Aminophyllin produces diuresis whether administered orally or parenterally, and thus has a field of usefulness covering emergencies and chronic congestive cardiac failure.

SEARLE AMINOPHYLLIN

contains at least 80% of anhydrous theophyllin.

G. D. Searle & Co., Chicago 80, Illinois

SPENCER
SUPPORTS

designed to aid
treatment of:

LOW-BACK PAIN

Spencer designers creat spinal supports varying from flexibility to rigidity, as prescribed.

VISCEROPTOSIS OR
NEPHROPTOSIS
WITH SYMPTOMS

Abdominal support in a Spencer is from below, upward and backward. It is accurately correlated with back support to effect posture improvement.

HERNIA

if inoperable, or when surgery is delayed. A Spencer improves the posture, gives support to the abdomen, and controls the hernia comfortably.

ANTEPARTUM
POSTPARTUM
POSTOPERATIVE

A Spencer provides whatever degree of abdominal support is required and gives restful support to back.

BREAST CONDITIONS

Spencer Breast Supports, like all Spencers, are individually designed to meet the specific needs of each patient.

You state your needs—we save you all bother as to proper design, fit, comfort. The Spencer you prescribe will be individually designed, cut and made after a description of the patient's body and posture has been recorded—and 15 or more measurements have been taken. This is an assurance that your requirements will be accurately met.

For a dealer in Spencer Supports look in telephone book for "Spencer corsetiere" or "Spencer Support Shop," or write direct to us.

Spencer Breast Support designed especially for this woman to support heavy, ptosed breasts.

REPORTS and ANNOUNCEMENTS

JACKSON CLINIC POSTGRADUATE MEETING

Dr. Karl Meyer of Chicago will address the next meeting of the Jackson Clinic Postgraduate Group to be held Thursday and Friday, May 16 and 17, at the Clinic.

The purpose of these refresher courses is to acquaint postgraduate members with the new developments in medicine as soon as their practical worth has been established. Every effort is made to present programs based on clinical work that may be used in everyday practice.

Any physician who is interested may attend. Veterans returning from service have an opportunity at this meeting to get a refresher course in civilian practice. Those wishing to attend should make reservation as soon as possible with the program chairman, Dr. Russell Jackson.

THURSDAY, MAY 16

Morning Session—9:00 A.M.

Clinical Interpretation of the Basal Metabolic Rate.
Demonstration of Technique of Basal Metabolism Test..........................Miss Lounsbury
Significance of the Basal Metabolic Rate in Hyperthyroidism............Dr. Arnold S. Jackson
Significance of the Basal Metabolic Rate in Hypothyroidism............Dr. Addie M. Schwittay
Significance of the Basal Metabolic Rate in Functional Disorders.........Dr. Russell Jackson
Clinical Interpretation of Laboratory Tests
Demonstration of Laboratory Tests ....Misses Hardy, Kelly, and Fay
Significance of Laboratory Tests;
Blood Dyscrasias......................Dr. Harold Marsh
Liver Dyscrasias......................Dr. Roger E. Henning
Kidney Dyscrasias....................Dr. Albert W. Bryan
Demonstration of Allergy Tests.
Significance of the Tests........Dr. Claude F. Schroeder
Demonstration of Allergy Tests. Significance of the Tests........Dr. Claude F. Schroeder, Dr. John A. Hurlbut

Luncheon—12:30 P.M.

Loraine Hotel. Round Table Discussion by the Morning Speakers.

Afternoon Session—2:00 P.M.

The Rh Factor......................Dr. Addie M. Schwittay
Demonstration of Blood Testing, Grouping Cross Matching, etc....................Laboratory Technicians
Diagnosis and Treatment of Sterility..Dr. Donald L. Dickerson
Diagnosis of Cancer of the Breast..........Dr. Russel Jackson
Lesions of the Genito-urinary Tract.......Dr. George H. Ewell
Treatment of Varicose Veins with Demonstration.....................Dr. Luther E. Holmgren

Dinner—6:30 P.M.

Loraine Hotel.
Address—Dr. Karl Meyer of Chicago
Color Motion Pictures of Mexico
Doctors' wives are invited to attend

FRIDAY, MAY 17

Morning Session—8:00 A.M.

Operative Clinic by Staff, Methodist Hospital.
Dry Clinic by Staff, Methodist Hospital.
Pre and Postoperative Care............Dr. Donald L. Dickerson
Recent Developments in Orthopedics....Dr. Arthur C. Stirling
Recent Developments in Surgery........Dr. Arnold S. Jackson

Luncheon—12:30 P.M.

Loraine Hotel. Round Table Discussion by the Morning Speakers.
Cancer of the Colon.......................Dr. James A. Jackson
Recent Developments in Pediatrics........Dr. Margaret Prouty
Problems in Gynecology...................Dr. Christine Thelen
Problems in Dietetics...........................Racheal Weirich
Case Presentations........Drs. Reginald H. Jackson, Michael DeSalvo, John H. Dix, and Elmer J. Hawkins
Sinus Disease..............................Dr. John A. Hurlbut
Meeting Adjourned

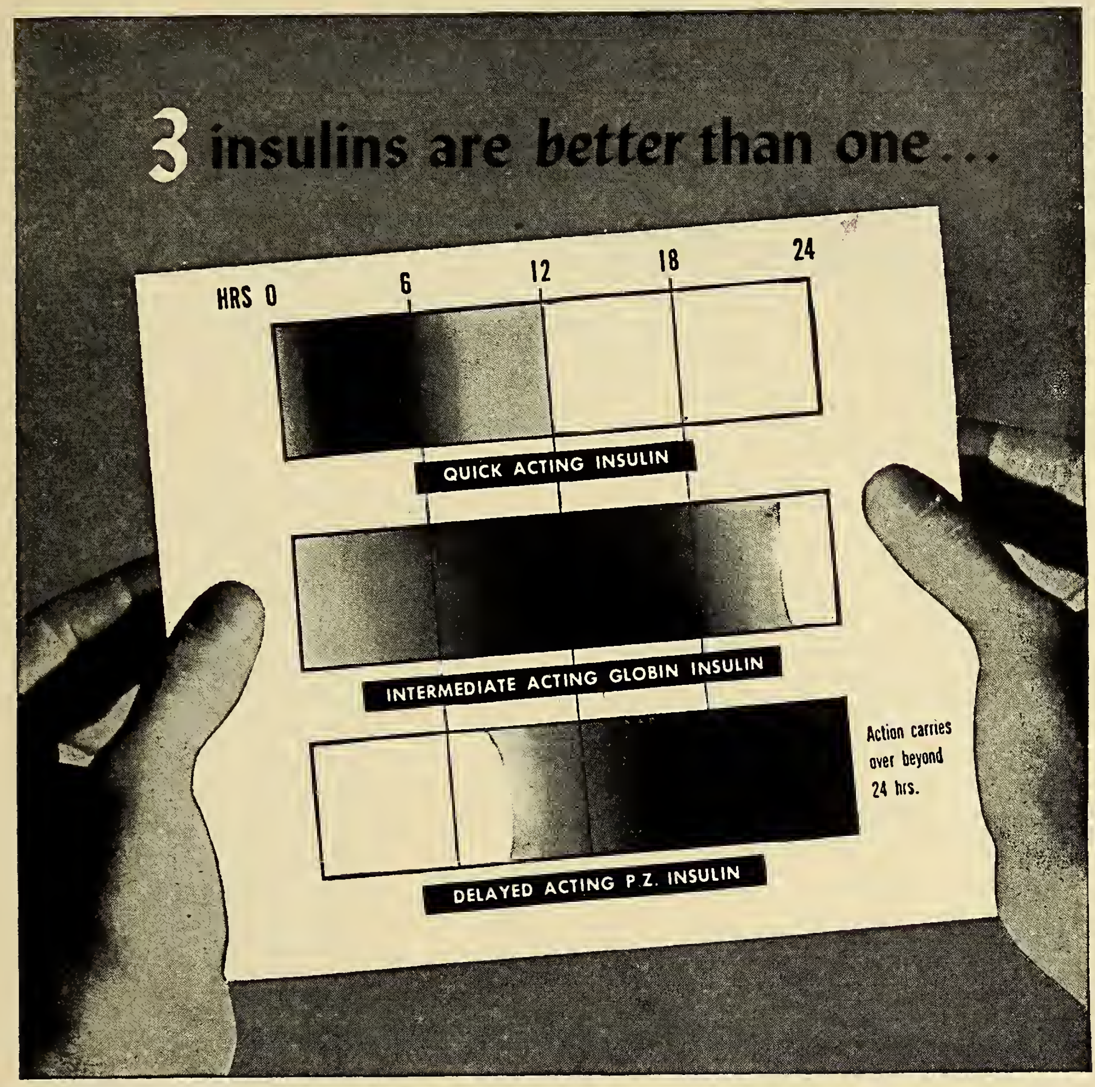
Lowry Medical Arts Building, St. Paul, Minnesota

FOR SALE BY SURGICAL DEALERS AND DRUGGISTS



THE PHYSICIAN treating diabetes today has the choice of three types of insulin. One is rapid-acting but short-lived. Another is slow-to-start but prolonged. Intermediate between them is the new 'Wellcome' Globin Insulin with Zinc which starts fairly promptly and continues *for sixteen hours or more*. Action is maximal during the times of major carbohydrate intake but diminished toward bedtime so that the likelihood of nocturnal reactions is decreased. Today, the physician is wise to consider all *three* insulins.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties.

Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in the Wellcome Research Laboratories, Tuckahoe, New York. U.S. Patent No. 2,161,198. Available in vials of 10 cc., *80 units in 1 cc.* and vials of 10 cc., *40 units in 1 cc.* Literature on request.

Stormy Weather

WHEN the menopausal storms set in—vasomotor disturbances, mental depression, unaccountable pain and tension—physicians today can take prompt, positive action to alleviate symptoms.

By the administration of a reliable solution of estrogenic substances, you may exert a gratifying measure of control.

For control of menopausal symptoms, you may turn with confidence to Solution of Estrogenic Substances, Smith-Dorsey . . . manufactured in the fully equipped, capably staffed Smith-Dorsey Laboratories . . . meeting rigid standards of purity and potency.

With such a medicinal, you can indeed *do something* about "stormy weather."

SOLUTION OF *Estrogenic Substances*

SMITH-DORSEY

Supplied in 1 cc. ampuls and 10 cc. ampul vials representing potencies of 5,000, 10,000 and 20,000 international units per cc.

WASHINGTON COUNTY

The Washington County Medical Society held its regular monthly meeting Tuesday, April 9, in Stillwater.

The different plans for prepayment medical insurance as proposed in the questionnaire sent out by the State Medical Association were discussed. Guests of the evening were Miss Madden, School Nurse, and Alice C. Gearty, the new County Nurse, who briefly outlined her work on the lines approved by the Minnesota State Medical Association and the State Health Department.

A movie on the subject of "Edema" was shown and proved very interesting.

WOMAN'S AUXILIARY

Mrs. Edward V. Goltz, *President*
Saint Paul, Minnesota
Mrs. John K. Butler, *Editor*
Carlton, Minnesota

ANNUAL STATE MEETING

A cordial invitation is extended to all Auxiliary members and visiting doctors' wives to attend the 24th Annual Meeting of the Woman's Auxiliary of the Minnesota State Medical Association, which will be held in St. Paul, May 20, 21 and 22. Auxiliary headquarters will be at the Lowry Hotel. Registration will take place both Monday, May 20 and Tuesday, May 21 at 9 A.M. Tickets for the various activities may be procured when registering. The Ramsey County Auxiliary has made most attractive plans for visiting women.

The Pre-Convention Board Meeting will take place at 11 A.M. Monday, May 20, at the Minnesota Club. That afternoon the officers will be honored at a Tea which will be held at the White Bear Yacht Club. Ramsey County members will be hostesses for this Tea, and all women are invited.

Tuesday morning at 10 A.M. the annual meeting will open at the Lowry Hotel. This will be followed by a luncheon at one o'clock. All doctors' wives are invited to attend the meeting and the luncheon. Reports of all committees and county residents will be read and election of new officers will be held. The guest speaker at the luncheon will be Dr. George M. Curtis, Professor of Surgery, Ohio State University College of Medicine, Columbus, Ohio.

Wednesday morning, at 10 A.M., the Ramsey County Auxiliary will entertain all visiting doctors' wives at a farewell breakfast at the Hotel Saint Paul.

Assisting Mrs. Wm. Van der Weyer, President of the Ramsey County Auxiliary, in making plans for the convention are Mrs. Charles W. Waas, General Chairman

Music—Mrs. Harry Zimmermann.

COUNTY AUXILIARY NEWS

Blue Earth

Mrs. H. Bradley Troost was elected president of Blue Earth Auxiliary on March 25 at the Mankato Clinic. The other officers for 1946-47 will be Mrs. George Penn, vice president, Mrs. W. Kinghorn, secretary, and Mrs. John Michelson, treasurer.

Mrs. J. E. Hues displayed articles of interest from India, Burma, and China.

A discussion on medical legislation was conducted.

Hennepin

Over 500 invitations were issued by the Woman's Auxiliary of Hennepin County to representatives of women's organizations to be guests at the fourth annual health meeting and tea on Friday, March 1, in the Medical Arts Lounge. Dr. Myron M. Weaver, acting assistant dean of the Medical School of the University of Minnesota, spoke on "Medical Practice in the Changing Social Order." Afterwards the guests were invited to ask questions and a lively discussion resulted. Mrs. Russell Morse was in charge of the meeting, and Dr. A. J. Campbell, president of Hennepin County Medical Society, introduced Dr. Weaver. Mrs. Reinhold M. Erickson and Mrs. Harold F. Wahlquist were social chairmen.

On February 28, the Medical Society and the Auxiliary held a joint dinner party and had a splendid time. More than 400 guests were present. The 250 club entertained. Mrs. Harvey Nelson was chairman of arrangements.

The Auxiliary will maintain a booth in the Medical Arts Building during the Cancer Fund drive.

Kandiyohi-Swift-Meeker

On March 21 the Auxiliary met at Lakeland Hotel, Willmar, and entertained those doctors' wives who do not belong to the Auxiliary. Kandiyohi-Swift-Meeker Auxiliary has nineteen members.

Mower

Mrs. W. B. Grise, Austin, was hostess to the Mower County Auxiliary on March 25.

Nicollet-Le Sueur

Mrs. H. B. Aitkens of Le Center was made an honorary member as a result of a decision made by the Nicollet-Le Sueur Auxiliary to honor wives of doctors

EMPHASIS ON BARRIER

AUTHORITATIVE clinical investigators place strong emphasis on the importance of the barrier in conception control.

In a recent comprehensive report[1] physicians indicated an overwhelming preference for the diaphragm and jelly method (93% of 36,955 new cases).

In keeping with these expressed opinions we continue to suggest that for the optimum in protection the physician prescribe the combined use of occlusive diaphragm and spermatocidal jelly.

You assure your patient a product of highest quality when you specify *Ramses* REG. U.S. PAT. OFF.

Competent observers report:

"Jellies and creams used without mechanical devices yield relatively high protection, but studies have not proven them fully dependable to block the external os, or to invalidate all sperm."[2]

"When no type of occlusive pessary can be fitted, or when the woman refuses to use one, the only other reliable method is the use of the condom. With proper technic and instruction this method is highly reliable but has many disadvantages which the diaphragm method overcomes."[3]

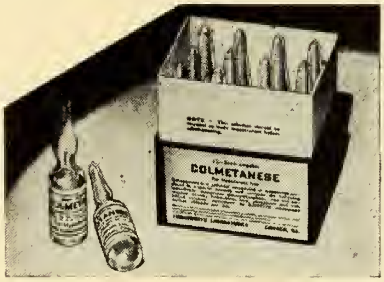
BRUCELLOSIS

(UNDULANT FEVER)

★ 10% of the population of this country has been infected — as estimated by Gould and Huddleson, 1938.

★ Brucellosis should always be suspected and ruled out, wherever low grade fever, or extreme fatigue, headaches, etc., are persistent. Investigators have stated that 25% of all chronic cases will react positive to Brucellosis, when tested.

★ Brucellosis now has been recognized as an important public health problem in this country, according to Carpenter.



COLMETANESE

Clinical reports from doctors who have treated their Brucellosis cases with Colmetanese are uniform.

COUNTY AUXILIARY NEWS

(Continued from Page 502)

who have completed fifty years of medical practice.

The Auxiliary met at the Cook-E-Jar, St. Peter, on March 20 for dinner. Afterwards a business meeting was held, at which plans were made for the annual cancer control drive. Members were also instructed on the part they are to take in opposing current medical legislation.

Olmsted-Houston-Fillmore-Dodge

Mrs. M. S. Henderson, president-elect of the State Medical Auxiliary, was honored on March 12 at a meeting held in Rochester. Mrs. E. V. Allen talked on the Murray-Wagner-Dingell Bill.

Plans were made for the annual Health Day for the lay public on April 23 at the Mayo Foundation House. Dr. A. R. MacLean of the Department of Neurology and Psychiatry of Mayo Clinic was the speaker.

Park Region

Auxiliary members were guests of the Medical Society at a dinner at River Inn Hotel, Fergus Falls, on March 21. The dinner was in honor of the doctors who had returned from the armed forces. Each doctor gave a brief account of some of his experiences.

Ramsey

Mrs. James L. Benepe presided at the March meeting held in the Ramsey County medical library auditorium on March 25. The social committee were hostesses. Dr. Myron Weaver was the speaker. The ladies also made surgical dressings.

Mrs. Wm. H. Von der Weyer, president, appointed Mrs. Charles W. Waas to be the general chairman of the State Medical meeting to be held in Saint Paul, May 20, 21, and 22. A tea, luncheon and style review, also a breakfast are among the plans being made to make the meeting pleasant for the visiting doctors' wives.

Renville

Renville County Auxiliary members met with the Medical Society at dinner at the Sweet Shop, Olivia, on March 12.

Redwood-Brown

A combined meeting of the Redwood-Brown Medical Society and Auxiliary was held at Turner Hall club rooms, New Ulm, in March. Dr. Carl Fritsche gave an interesting report of his experiences as Flight Surgeon in World War II. He also showed some movies.

St. Louis

Mrs. Mark Tibbetts was hostess to St. Louis County Medical Auxiliary on Tuesday, March 12. Mrs. A. T. Laird gave an enthusiastic review of Adamic's "A Nation of Nations." Mrs. H. E. Bakkila was in charge of the social committee. Mrs. G. Arvid Hedberg presided and presented plans for an open meeting in May at which Dr. Myron Weaver will talk.

Stearns-Benton

Mrs. W. T. Wenner, St. Cloud, was hostess to the Stearns-Benton Auxiliary on March 12. Mrs. J. C. Buscher gave a report on the cancer control course conducted at the Continuation Center.

Washington

Mrs. C. H. Sherman, Bayport, entertained the Auxiliary on March 12. Ten members and two guests were present. A slate of new officers was drawn up.

YOU CAN'T OVERRATE THE VALUE OF CONTROL

When you come to think of it, it's surprising how much control means. In various forms it adds enjoyment to sports—security to daily routine—satisfaction to work of skill.

And as *quality control* it assures safety in medicines. This is particularly well demonstrated in the development and production of U.D. pharmaceuticals. For throughout modern U.D. laboratories and plants a carefully conceived and remarkably efficient system of tests and checks results in products with an enviable reputation for consistent excellence.

Credit for maintenance of these high standards rests with a body of doctors, chemists and pharmacists, known as the Formula Control Committee. As the ultimate precaution, this group personally checks every finished product.

Such professional attention insures that your prescriptions are filled with finest ingredients when you specify U.D. pharmaceuticals. Your neighborhood Rexall Drug Store offers this service—together with complete facilities for meeting your patients' needs reliably and economically.

Effective
Convenient
Economical

THE effectiveness of Mercurochrome has been demonstrated by more than twenty years of extensive clinical use. For professional convenience Mercurochrome is supplied in four forms—Aqueous Solution in Applicator Bottles for the treatment of minor wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

Mercurochrome

(H. W. & D. brand of merbromin, dibromoxymercurifluorescein-sodium)

is economical because stock solutions may be dispensed quickly and at low cost. Stock solutions keep indefinitely.

Mercurochrome is antiseptic and relatively non-irritating and non-toxic in wounds.

Complete literature will be furnished on request.

In Memoriam

CHARLES CRAWFORD ALLEN

Dr. Charles Crawford Allen of Austin, Minnesota, died at the age of sixty on February 20, 1946, of coronary thrombosis, after thirty-five years of active medical practice in Minnesota.

Because of his genuine love of his fellow man, manifested daily by his quiet appreciation of the small comedies and tragedies of life that are unveiled only for the trusted physician, Dr. Allen was able to serve the art of Medicine as it should be served. He did not spare himself or attempt to avoid hardships when the welfare of the patient demanded his attention. "Maintain life, restore the sick and ease the suffering of men. You have no other object."

Those who have known him professionally and personally will recognize in his death the loss of a true "specialist in general practice"—one whose knowledge is deep enough and broad enough to give the maximum benefit to all patients who present themselves for treatment, and yet a knowledge that is tempered with wisdom and a keen appreciation of human inadequacies, found even in physicians, so that one is able to say "I do not know." It is significant that in his brief case at the time of his sudden, fatal illness, Dr. Allen carried a set of notes on tropical medicine, compiled at an army service school and loaned to him at his own request. He recognized the need for a personal refresher course in order to cope with diseases among returning veterans that might prove new and strange to one who had practiced solely in a northern climate.

Dr. Allen was born December 1, 1885, at Grand Rapids, North Dakota, and spent his boyhood at Ada, Minnesota, where he was graduated from high school. He later attended Carleton College and the University of Minnesota Medical School. He served his internship at Ancker Hospital, St. Paul, and practiced for a short time in 1911 at Pipestone before coming to Austin. His practice in Austin was interrupted by World War I, when he served in the army medical corps, attaining the rank of Captain. On his discharge in 1919, he, Dr. W. B. Grise, the late Dr. C. F. Lewis and the late Dr. E. C. Rebman, founded the Austin Clinic of which he remained an active member until his death.

Dr. Allen was active in organizations associated with his profession. He was past president of the Southern Minnesota Medical Society and the Mower County Medical Society, and a member of the Minnesota State Medical Association and the American Medical Association. He formerly served as city health officer, county physician, and chief-of-staff of St. Olaf Hospital, Austin.

(Continued on Page 510)

ADHERENCE TO A STANDARD

There are few more important activities than the production of medicaments for the relief of human ills—and none wherein the implications of responsibility are more profound.

Mass production on the grand scale is not necessarily an assurance of clinical efficacy. Doing a few things superlatively well provides products which merit deserved confidence.

Favored with an environment almost ideal for the important work being performed; guided by a staff of forward-thinking scientists; operated by personnel whose undiverted interest occupies each day, U. S. Standard Products Company are producing a selected and therapeutically efficient list of distinguished essentials for the medical profession.

OUTSTANDING U. S. STANDARD BIOLOGICALS:

DIPHTHERIA TOXOID

•

TETANUS ANTITOXIN

•

SMALL POX VACCINE

•

TYPHOID VACCINE

Also a representative list of glandular products and pharmaceuticals.

U. S. STANDARD PRODUCTS CO.

WOODWORTH, WISCONSIN, U. S. A.

CHARLES CRAWFORD ALLEN

(Continued from Page 508)

He was also one of the profession's most active members in the community affairs, being identified with most of Austin's civic organizations. He was a member of the Austin American Legion post, Chamber of Commerce, Rotary Club, Austin Country Club, and had been active in the promotion of Boy Scout activities. A member of the Congregational Church, he served as a trustee and sang in the choir. He was also a trustee of Carleton College.

Doctor Allen is survived by his wife, Mrs. Mary S. Allen, and a son, Charles M. ("Chuck") Allen. "Chuck" Allen is twenty-one years of age and is now attending the University of Minnesota. He was a B-17 pilot during the war and was shot down over Germany. He was a prisoner of war for almost one year, and there was a long period of time when Dr. Allen did not hear from him. It was a source of comfort to his friends that Doctor Allen survived long enough to see "Chuck" back in good health and reasonably settled as far as his life work was concerned.

"He cures most in whom most are confident."

David P. Anderson, M.D.

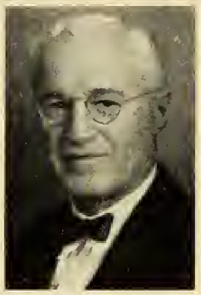
HENRY O. GRANGAARD

Dr. Henry O. Grangaard of Proctor, Minnesota, died recently of a heart attack in Jamestown, North Dakota. Born in Kindred, North Dakota, February 24, 1882, Dr. Grangaard graduated from Luther College, Decorah, Iowa, in 1902 with a B.A. degree, and from the University of Minnesota Medical School in 1908.

He practiced at Newark, Illinois, from 1908 to 1910; at Douglas, North Dakota, from 1910 to 1922, and at Ryder, North Dakota, from 1922 to 1943. In 1943 he moved to Proctor, St. Louis County, where he was on the medical staff of the State Hospital.

HAROLD E. ROBERTSON

Dr. Harold E. Robertson, Senior Consultant of the Section on Pathologic Anatomy of the Mayo Clinic, died March 8, 1946, after a brief illness.



Dr. Robertson was born October 8, 1878, at Waseca, Minnesota. He received the degree of B.A. in 1899 from Carleton College, Northfield, and of M.D. in 1905 from the University of Pennsylvania. He was an intern at the University of Pennsylvania Hospital for four months and was an assistant to Dr. Richard Pearce at Albany, New York, and an instructor in pathology at Albany Medical College, from 1905 to 1906. He was assistant pathologist, Boston City Hospital, from 1906 to 1907 and was appointed an instructor in pathology in Harvard University. He came

HAROLD E. ROBERTSON

(Continued from Page 510)

to the University of Minnesota Medical School in 1907 as instructor in pathology and bacteriology. He became assistant professor of pathology and bacteriology in the university in 1909 and associate professor in 1910, and was professor of pathology there from 1914 to 1921. He was also director of the Department of Pathology, Bacteriology and Public Health at the University of Minnesota Medical School from 1917 to 1921. He took courses in pathology at the University of Berlin and the University of Freiburg in 1914 and 1915.

From 1917 to 1919 Dr. Robertson was a major in the Medical Corps of the American Expeditionary Force. During this service he was stationed at Army Laboratory I for six months, and at the Central Medical Department Laboratory at Dijon for six months and was consulting pathologist in the district of Paris for six months.

He entered the Mayo Clinic as head of the Section on Pathologic Anatomy July 1, 1921, at which time he was transferred as professor of pathology from the University of Minnesota Medical School to the Mayo Foundation. He held these positions until October 1, 1943, when he became a senior consultant in the same section at the clinic.

On July 31, 1907, he was married to Edith Ellam who survives him.

Dr. Robertson was a fellow of the American College of Physicians; a member of the American Society for the Control of Cancer, the Minnesota Academy of Medicine, the American Association of Pathologists and Bacteriologists (past president), the American Medical Association, the International Association of Medical Museums, the Alumni Association of The Mayo Foundation, Sigma Xi, Phi Beta Kappa, and Alpha Omega Alpha. He was a member of the Board of Directors of the American Society for the Control of Cancer.

CHESTER A. STEWART

Dr. Chester A. Stewart, formerly of Minneapolis, but since 1941 Director of the Pediatric Department of the Louisiana State University Medical School, died recently in New Orleans.

Born in Hannibal, Missouri, November 6, 1890, Dr. Stewart attended the University of Missouri at Columbia, Missouri, from which he received the degrees of A.B., A.M., and Ph.D. His medical degree was obtained from the University of Minnesota in 1920. After interning at the Gillette State Hospital, Saint Paul, Minnesota, he took five years of postgraduate work in anatomy and pediatrics at the University of Minnesota and the Mayo Foundation. He was a member of Sigma Xi.

While living in Minneapolis, Dr. Stewart was Clinical

A REMARKABLE development which assures accuracy in auscultory diagnosis.

An electronic stethoscope which amplifies the faint heart and chest sounds you wish to hear while subduing the other sounds to convenient levels for comparison.

Easily detects faint murmurs and disease sounds which cannot be heard through the old-fashioned acoustic stethoscope.

A demonstration will convince you.

Professor of Pediatrics and Director of the Pediatric Out-Patient Department of the University of Minnesota Medical School, and Consultant at the Lymanhurst Health Center. He was a former president of the Hennepin County Medical Society and a Councilor for the Sixth District of the Minnesota State Medical Association. He was chosen as a delegate to the Fourth International Congress of Pediatrics at Rome in 1937, and also served as a member of the White House Conference on Child Health and Protection. A member of the National Tuberculosis Association's committee on diagnostic standards, he was much interested in the control of tuberculosis and the plan of county accreditation in tuberculosis work in the state. He returned to Minneapolis upon invitation in May, 1942, to be the principal speaker at the Olmsted County accreditation ceremonies.

Dependable Estrogen Therapy with

Schieffelin
BENZESTROL
(2, 4-di (p-hydroxyphenyl)-3 ethyl hexane)

For the relief of menopausal symptoms, for senile vaginitis, for the suppression of lactation, and as a supplementary agent in the treatment of gonorrheal vaginitis in children, estrogen therapy has proved highly beneficial. A dependable means of administering such therapy may be found in Schieffelin BENZESTROL.

This synthetic estrogen has proved valuable in effecting more rapid and gratifying results where estrogen therapy is indicated.

Schieffelin BENZESTROL is available for oral, parenteral and local administration.

Literature and Sample on Request

Schieffelin BENZESTROL Tablets:
Potencies of 0.5, 1.0, 2.0 and 5.0 mg.
Bottles of 50, 100 and 1000.

Schieffelin BENZESTROL Solution:
Potency of 5.0 mg. per cc. in 10 cc.
Rubber Capped Multiple Dose Vials

Schieffelin BENZESTROL Vaginal Tablets:
Potency of 0.5 mg. Bottles of 100

Of General Interest

Dr. Robert W. Merrill has been discharged from the Navy and has re-opened his office in Morris.

* * *

Dr. Thomas Magath, of the Mayo Clinic, presented a paper on "Diseases of International Importance" at the April meeting of the Medical Forum in Saint Paul.

* * *

Dr. Wayne C. Canfield, of Houston, is now associated in the practice of medicine and surgery with Dr. George M. Ruggles, of Forest Lake.

* * *

Dr. Canfield, who was recently discharged from the Transportation Corps, with duty in New Orleans and San Francisco, has been practicing for fifteen years.

* * *

Dr. George A. Sather, Fosston, is one of the board of seven men selected to formulate plans for a large new hospital for Fosston, which is expected to be accredited under the Blue Cross plan.

* * *

Dr. George L. Joyce has returned to his practice in Rochester after two and a half years in military service. As a commander in the Navy, Dr. Joyce was on duty in Chicago, Biak and the Admiralty Islands.

* * *

The Board of Regents of the University of Minnesota has announced the appointment of Dr. Richard V. Ebert to an associate professorship in medicine. Dr. Ebert will be engaged in both teaching and research.

* * *

Colonel Harry P. Harper, a fellow in surgery at the Mayo Foundation from 1940 to 1941, has been granted the Legion of Merit award for his work in establishing the first field hospital across the Rhine.

* * *

Dr. Thomas Ziskin has resumed the practice of internal medicine with offices in the Medical Arts Building. Dr. Ziskin, a major in the Army, entered service in April, 1944, when he was assigned to the Veterans Hospital in Minneapolis.

* * *

Crow Wing County was represented at the midwinter Commencement Exercises at the University of Minnesota by Harold D. Kletschka, Lake Hubert, and Alice Marie Lund, of Pequot Lakes. Both received Bachelor of Science Degrees from the School of Medicine.

* * *

Dr. J. T. Anderson, of Chisholm, has taken over the practice of Dr. Frank M. Petkevich at Red Lake Falls. Dr. Anderson was recently discharged from the Navy where he was a lieutenant commander. He is a graduate of the University of Minnesota Medical School.

* * *

Minnesota was represented in the medical graduates at the commencement exercises of Northwestern University on March 15 by John P. Utz, of Rochester. Dr. Utz began his internship at the Massachusetts Memorial Hospital on April 1.

* * *

Dr. Malcolm Mollison, son of A. E. Mollison, of Faribault, who received his doctor's degree from the Oklahoma University School of Medicine, has been appointed to an internship at St. Joseph's Hospital in Saint Paul.

* * *

Dr. Harold T. Gustafson has returned from two and a half years in the Navy and has re-opened his office in the La Salle Building in Minneapolis. With the rank of commander, Dr. Gustafson was head of surgery on the AP'AH *Joseph T. Dickman* for the past year.

* * *

Dr. John J. Bittner, who holds the George Chase Christian Professorship of Cancer Biology at the University of Minnesota Medical School, was elected vice president of the American Association for Cancer Research at the recent meeting held at Atlantic City.

* * *

Dr. Archibald H. Logan, a staff member of the Mayo Clinic for over thirty-five years, has been retired from active service, having reached retirement age. Dr. Logan, who has been head of a section in medicine since 1911, joined the Clinic on January 1, 1910.

* * *

Dr. C. F. Anderson, of Cloquet, has joined Dr. Roman V. Fait and Dr. Douglas L. Johnson in the practice of medicine at Little Falls. A graduate of the University of Minnesota Medical School, Dr. Anderson was only recently discharged from military service.

* * *

Dr. and Mrs. Myron Lysne and children have returned to their home in Robbinsdale from Oklahoma City, Oklahoma, where Dr. Lysne was stationed at Will Rogers Field. A major in the Army Medical Corps, Dr. Lysne was in service for four years.

* * *

Dr. E. G. Howard, who closed his office in Mapleton more than two years ago when he was inducted into the Navy, has returned home and is again in practice. A lieutenant commander, Dr. Howard served on an LST in the Atlantic and an AKA in the Pacific.

* * *

Dr. Thomas J. Dry has returned to his position on the staff of the Mayo Clinic from three and a half years of military service. A lieutenant in the Army Medical Corps, Dr. Dry was stationed at Camp Carson, Colorado Springs, Colorado.

* * *

Dr. Thomas J. Kinsella was made president of the Minneapolis Society of Surgeons at a recent meeting. Other officers elected were: Dr. Carl Rice, vice pres-

Today, more
than ever . . .
Doctors Appreciate the
Importance of
HANOVIA
ULTRA-VIOLET
QUARTZ LAMPS
As Part of Their Standard
Office Equipment

AMERICAN MEDICAL ASSN. ACCEPTED COUNCIL ON PHYSICAL THERAPY

NON-TILTING — INSTANT LIGHTING — FAST ACTING

Like all Hanovia mercury quartz generators the burner of the Luxor "S" Alpine Lamp delivers the COMPLETE mercury spectrum in the invisible ultraviolet. The complete spectrum with high intensity emission is DEFINITELY required for general therapeutic use.

This lamp is designed to give a complete irradiation of one side of the body at one exposure. Erythemic reactions are uniform over the body. The time required is 30 seconds on average untanned skin, at 30 inches distance. The intensity is constant and the lamp can be moved about when lighted without extinguishing the arc.

This Lamp Has a Wide Range of Clinical Usefulness

TUBERCULOSIS: Irradiation is of distinct value for patients suffering from tuberculosis of the bones, articulations, peritoneum intestine, larynx and lymph nodes or from tuberculous sinuses.

SKIN DISEASES: Ultraviolet radiation acts specifically on lupus vulgaris and often has a beneficial effect in such conditions as acne vulgaris, eczema, psoriasis, pityriasis rosea and idolent ulcers.

SURGERY: Sluggish wounds that do not heal or are abnormally slow in healing may respond favorably to local or general irradiation.

CARE OF INFANTS AND CHILDREN: The prophylactic and curative effects of ultraviolet radiation on rickets, infantile tetany or spasmophilia and osteomalacia are well known.

PREGNANT AND NURSING MOTHERS: Prenatal irradiation of the mother and also irradiation of the nursing mother, have a definite preventive influence on rickets.

OTHER APPLICATIONS: As an adjuvant in the treatment of secondary anemia, irradiation merits consideration. Also exposure of the lesions of erysipelas and a wide area of surrounding tissue has been shown to have a favorable effect.

Complete information about Hanovia Therapeutic Apparatus will be sent promptly upon request.

ident; Dr. Edwin R. Anderson, secretary; Dr. Hamlin Mattson, recorder, and Dr. Haynes Fowler and Dr. John Payne, members of the board of directors.

* * *

According to an announcement issued by Dr. William A. O'Brien, Director of Public Health Study at the University of Minnesota, Minnesota had a lower pneumonia and influenza rate during January and February than any other area in the United States.

* * *

Announcement has been made of the appointment of Dr. J. Emery Frank, of Marshall, as a Veterans Administration physician for the area. Until his release several months ago, Dr. Frank was a flight surgeon in the Army Air Corps.

* * *

For the first election in thirty-six years, Dr. John Crewe, Stewartville, will not be a candidate for coroner of Olmstead County, an office in which he has succeeded himself consecutively every four years since he was first elected on January 1, 1911. Ill health is Dr. Crewe's reason for declining to file.

* * *

Dr. Hermanus De Boer, of Edgerton, whose illness was at first reported as serious, is now improving steadily. He is able to be up and around his home for most of the day and he is generally free from pain. Dr. De Boer has been in continuous practice in Edgerton for the past forty years.

* * *

Dr. R. J. Mattich, who recently completed his interneship at St. Mary's Hospital in Duluth, has joined the staff of the Mesaba Clinic Hospital in Chisholm, and expects to remain there until called into military service. Dr. Mattich comes from Pringar, Iowa, and he is a graduate of the University of Iowa Medical School.

* * *

Dr. Arthur M. Mulligan has returned to Brainerd from postgraduate study at the University of Nebraska and has re-opened his offices for the practice of medicine and surgery. Dr. Mulligan was a member of the Army Medical Corps for five years and served forty-two months in the Pacific Theatre.

Dr. Stanley T. Kucera, of Lonsdale, is erecting a modern brick building in Northfield, where he will be associated in practice with Dr. Ariel E. Nielsen, of Northfield. Dr. Kucera, who is prominent in Rice County Medical activities, is a member of the staff of the Northfield Hospital.

* * *

Dr. Robert J. Richardson, formerly of Rushford, has opened offices for general practice at 2395 University Avenue, Saint Paul. Dr. Richardson was only recently released from the Army after four and a half years in service. A captain, he was on duty with the Sixth Infantry Division in the Pacific. He is a graduate of the University of Minnesota Medical School, Class of 1938.

* * *

Discharged last February after forty-two months of military service, Dr. Frederick D. Roth has resumed his practice in Lewiston. A captain in the army, Dr. Roth's assignments included duty at the Central Flying Training Command at Randolph Field, Texas, and two and a half years with the British Flying Training School at Miami, Oklahoma.

* * *

Dr. John M. Grogan, who was recently discharged from military service, has located in Ceylon. Following his graduation from the University of Minnesota Medical School, Dr. Grogan served his internship in Kansas City, Missouri. From there he was inducted into the Army, where he served for two years. Dr. Grogan is the son of Dr. John S. Grogan, of Wadena.

* * *

Dr. William H. Bickel and Dr. J. Grafton Love, of the Mayo Clinic, presented papers at the sectional meeting of the American College of Surgeons held in Salt Lake City. Dr. Bickel's subject was "Plantar Neuromas," and Dr. Love discussed "Present Status of Intervertebral Disks." During the same week Dr. Bickel attended the sectional meeting in Portland, where he spoke on "Cup Arthoplasty of the Hips."

* * *

Following his discharge from military service on March 4, Dr. Charles Anderson, of Duluth, joined the staff of Shipman Hospital at Ely. Out of four years of duty, Dr. Anderson spent twenty-one months in New

Dr. William O'Brien, Director of Postgraduate Medical Education at the University of Minnesota, was re-elected president of the Minnesota Cancer Society at the annual meeting of the board. Other officers elected were: Dr. Henry B. Clark, Jr., and Dr. Arthur H. Wells, Duluth, vice presidents; Cleon Headley, Saint Paul, second vice president; Mrs. T. M. Olson, Elk River, commander of the cancer field army; Mrs. George W. Lawson, Saint Paul, secretary, and Louis Hill, Jr., Saint Paul, treasurer.

James H. Baker, executive secretary of the Hennepin County Medical Society and Mrs. M. A. Hessian, Minneapolis, were elected members of the executive committee.

* * *

The Hennepin County Medical Society reports the return to practice of the following Minneapolis physicians:

Dr. Martin Aune, eye, ear, nose and throat specialtist, has offices in the La Salle Building. Dr. Aune served as medical director of the Twin Cities Ordnance Plan for fifty-six months.

Dr. Alfred N. Bessesen, Jr., has resumed general practice in his offices in the Medical Arts Building. A commander in the Navy, Dr. Bessesen was inducted in September, 1943, and served at the Great Lakes Naval Hospital, Oakland Naval Hospital, and with a fleet hospital in the Philippines.

Dr. George C. Brutsch has re-opened his offices at 2550 Bloomington Avenue. With the rank of major, Dr. Brutsch served thirty months with an ordnance battalion in the ETO.

Dr. Raymond W. Dowidat has returned to his offices at 620 West Sixty-sixth Street, after almost four years of service. A captain in the Army Medical Corps, he was battalion surgeon with the 43rd Division in the Solomons, New Guinea, the Philippines and Japan.

Dr. Vernon L. Hart has resumed the practice of orthopedics in his offices in the Medical Arts Building. A lieutenant colonel, Dr. Hart entered the army in April, 1942, and served at Fitzsimons General Hospital and as orthopedic consultant for the Seventh Service Command at Camp Carson, Colorado.

Dr. Conrad J. Holmberg has resumed his practice in diseases of the eye, ear, nose and throat, with offices in the Medical Arts Building. Dr. Holmberg, a lieutenant colonel, entered the Army in February, 1942, and served overseas for forty months in New Caledonia, Okinawa and Korea with the 31st Station Hospital.

Dr. Harry A. Johnson has re-opened his offices in the La Salle Building. A commander in the Navy, Dr. Johnson was inducted in May, 1943. He was assigned to an LST in the Pacific for a year and participated in five invasions.

Dr. Abraham B. Litman has resumed his practice at 333 East Hennepin Avenue. Dr. Litman has been in service since September, 1942. With the rank of captain he was on duty at station hospitals in Los Angeles and Ft. Missoula, Montana, and with a hospital train.

Dr. Stanley W. Lundblad has returned to his offices the Medical Arts Building. A major in the Army, Dr. ındblad entered service in February, 1942, and served r forty months with the 31st Station Hospital in New ledonia, Okinawa and Korea.

Dr. William P. Sadler has re-opened his offices for e practice of obstetrics and gynecology in the Medical rts Building. A commander in the Navy, Dr. Sadler as assigned to a Naval Hospital in this country in ay, 1942, and later was staff officer for a service uadron in the Pacific.

Dr. Bernard I. Saliterman has resumed the practice of stetrics and gynecology in his offices in the La Salle ıilding. Dr. Saliterman entered the Army in July, 43, and with the rank of captain served with the 71st vacuation Hospital in New Guinea and the United ates.

Dr. Desmond M. Thysell has re-opened his offices for neral practice at 354 Thirteenth Avenue N. E. Dr. nysell entered service in July, 1943, and was battalion rgeon with a Marine combat unit in the South Pacific.

HOSPITAL NEWS

At the expiration of his terminal leave from the Navy, r. Ralph Rossen will return to his duties as superin- ndent of the Hastings State Hospital. Dr. Rossen ined the Navy in May, 1943, and with the rank of lieu- nant commander was in charge of the Division of ectro-encephalography at the U. S. Naval Hospital at ortsmouth, Virginia.

A graduate of the University of Minnesota, Dr. Rosen widely known as one of the co-developers of the Kabat-Rossen-Anderson apparatus for the treatment of schizophrenia, which was used by the Navy Submarine Division in the medical study of deep sea divers. He is a member of the American Board of Neurology and the American Board of Psychiatry.

* * *

Miss Patricia Streeter, R.N., of St. Cloud, who was recently discharged from the Army after eleven months of duty in the Philippines, is now associated with the Veterans Hospital in Minneapolis.

* * *

The offices of Olmsted County Public Health Nurses have been moved from the courthouse to the Rochester city hall. In commenting on the move, Dr. Floyd M. Feldman, city health officer, explained that it was done so that nurses of both the city and the county would be able to work as a single unit. The work will continue to be under the supervision of Miss Mildred Mouw.

Veterans Hospitals in Need of Physicians

(Continued from Page 525)

at salaries ranging from $3,640 to $5,180, according to E. R. Benke, deputy administrator of Branch-8.

Specialists certified by the American Specialty boards of the VA will be paid an additional 25 per cent of base pay.

Managers of regional offices and hospitals have been authorized by Washington to fill positions in junior, associate and full grade.

Close association with civilian medical associations and teaching centers will assure modern scientific medicine in VA establishments, it is believed.

"The large number of patients handled, and the opportunity for continuity of contact with individual patients over a period of years, provides outstanding opportunity for extensive professional experience," Mr. Benke said.

Interested physicians are asked to apply to the manager of the nearest regional office, hospital or center, or to the branch office, 328 Midland Bank Building, Minneapolis. Preference of location will be given consideration consistent with the needs of the service.

PERSONALIZED DUPLICATE-SIX RECEIPTS—Your Name, Profession, Phone and Address printed on each receipt at no additional cost over ordinary receipts. 504 receipts in duplicate to a book—book lies flat when opened. Price—One book, $2.25. Samples and quantity prices by request. Spillane's, 2121 Chicago Avenue, Minneapolis 4, Minnesota.

8 hours' release

Even overwrought patients who "fight off" sleep are lulled gently but firmly with Ipral. The effect is not apt to wear off suddenly, as with the shorter-acting barbiturates. Ipral assures a full night's sleep, closely resembling the normal. Prescribe one or two tablets of Ipral Calcium (calcium ethylisopropyl barbiturate) *one hour before retiring*. Plain, unmarked, unidentifiable.

TRADEMARK **Ipral** CALCIUM

SQUIBB

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

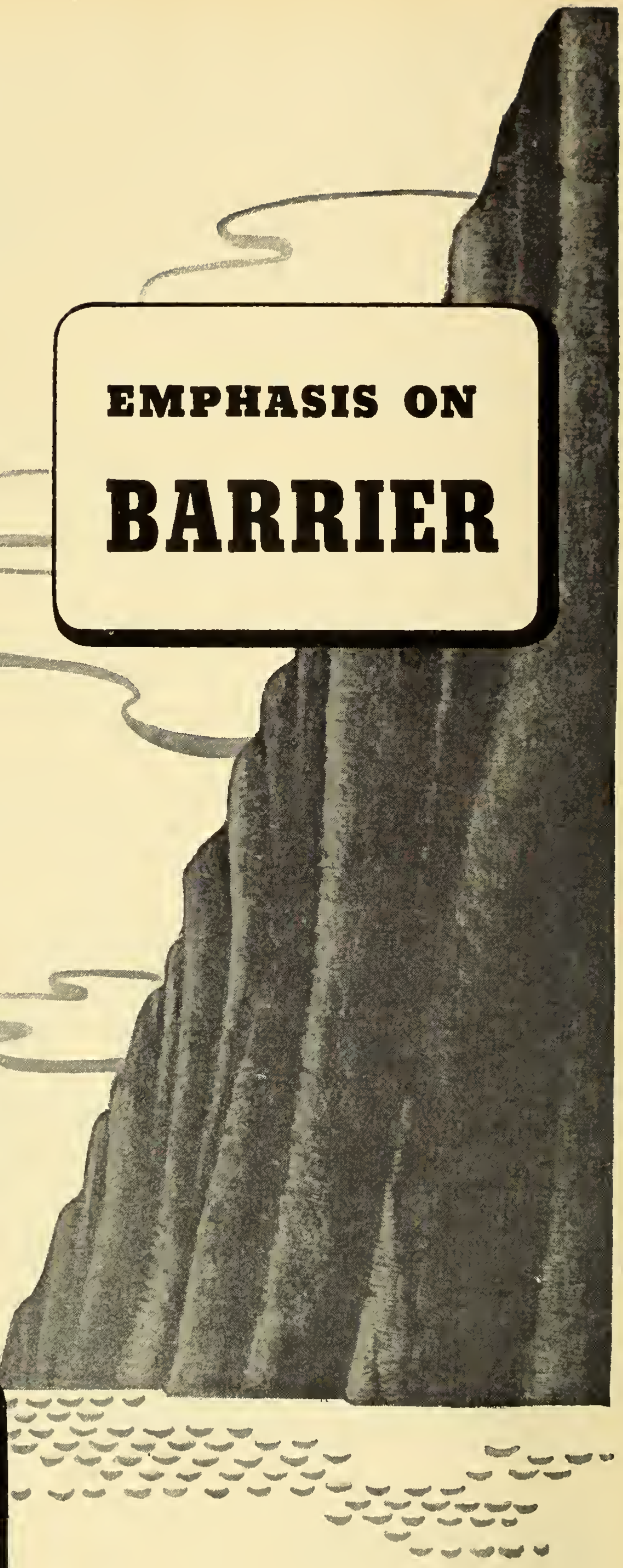
EMPHASIS ON BARRIER

AUTHORITATIVE clinical investigators place strong emphasis on the importance of the barrier in conception control.

In a recent comprehensive report[1] physicians indicated an overwhelming preference for the diaphragm and jelly method (93% of 36,955 new cases).

In keeping with these expressed opinions we continue to suggest that for the optimum in protection the physician prescribe the combined use of occlusive diaphragm and spermatocidal jelly.

You assure your patient a product of highest quality when you specify *Ramses* REG. U.S. PAT. OFF.



Competent observers report:

"Jellies and creams used without mechanical devices yield relatively high protection, but studies have not proven them fully dependable to block the external os, or to invalidate all sperm."[2]

"When no type of occlusive pessary can be fitted, or when the woman refuses to use one, the only other reliable method is the use of the condom. With proper technic and instruction this method is highly reliable but has many disadvantages which the diaphragm method overcomes."[3]

CLAIMS

VS.

DIFFERENCES

WHAT value have claims of superiority unless there is a difference in formula or process to justify such claims?

Take cigarettes for example.

PHILIP MORRIS Cigarettes are *made* differently. In the clinic as well as in the laboratory, the *advantages* of PHILIP MORRIS have been repeatedly observed, repeatedly reported by *recognized authorities* in leading medical journals. Yes, PHILIP MORRIS *claims* superiority . . . *and that superiority has been proved.**

May we suggest that your patients suffering from irritation of the nose and throat due to smoking change to PHILIP MORRIS—*the one cigarette proved definitely less irritating.*

NOW THAT PENICILLINASE SCHENLEY

IS AVAILABLE TO CHECK RESULTS

Penicillinase

- In determining the progress of penicillin therapy, inhibitory concentrations of penicillin in the blood and other body fluids may prevent satisfactory culture of infecting organisms. But Penicillinase Schenley will inactivate the penicillin in an hour's time. Penicillin-sensitive bacteria can then grow and a dependable bacteriologic evaluation be made.

- Penicillinase Schenley is now produced in quantities sufficient to supply the needs of all medical laboratories.

- It is the latest product of Schenley Laboratories' research program, which to date has borne fruit in superior penicillin and penicillin products.

Silencer for midnight phones

When pediatricians prescribe 'Dexin' brand High Dextrin Carbohydrate for their infant patients, the physicians are no longer wakened so frequently by frantic late-night phone calls. Because of the high dextrin content, 'Dexin' feedings tend to (1) diminish intestinal fermentation and the resultant colic and diarrhea and (2) promote the formation of soft, flocculent, easily digested curds.

'Dexin' babies sleep more soundly, physicians' phones jangle less, and the doctor himself obtains more undisturbed sleep. Not unpalatably sweet, 'Dexin' is readily soluble in hot or cold milk or other bland fluids. 'Dexin' does make a difference.

'Dexin'

HIGH DEXTRIN CARBOHYDRATE

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available Carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

MAINTAIN HIGH PENICILLIN TIDE
IN THE BLOOD STREAM
BY ONE INJECTION IN 24 HOURS
WITH ROMANSKY FORMULA
. . . OFFERED BY BRISTOL LABORATORIES

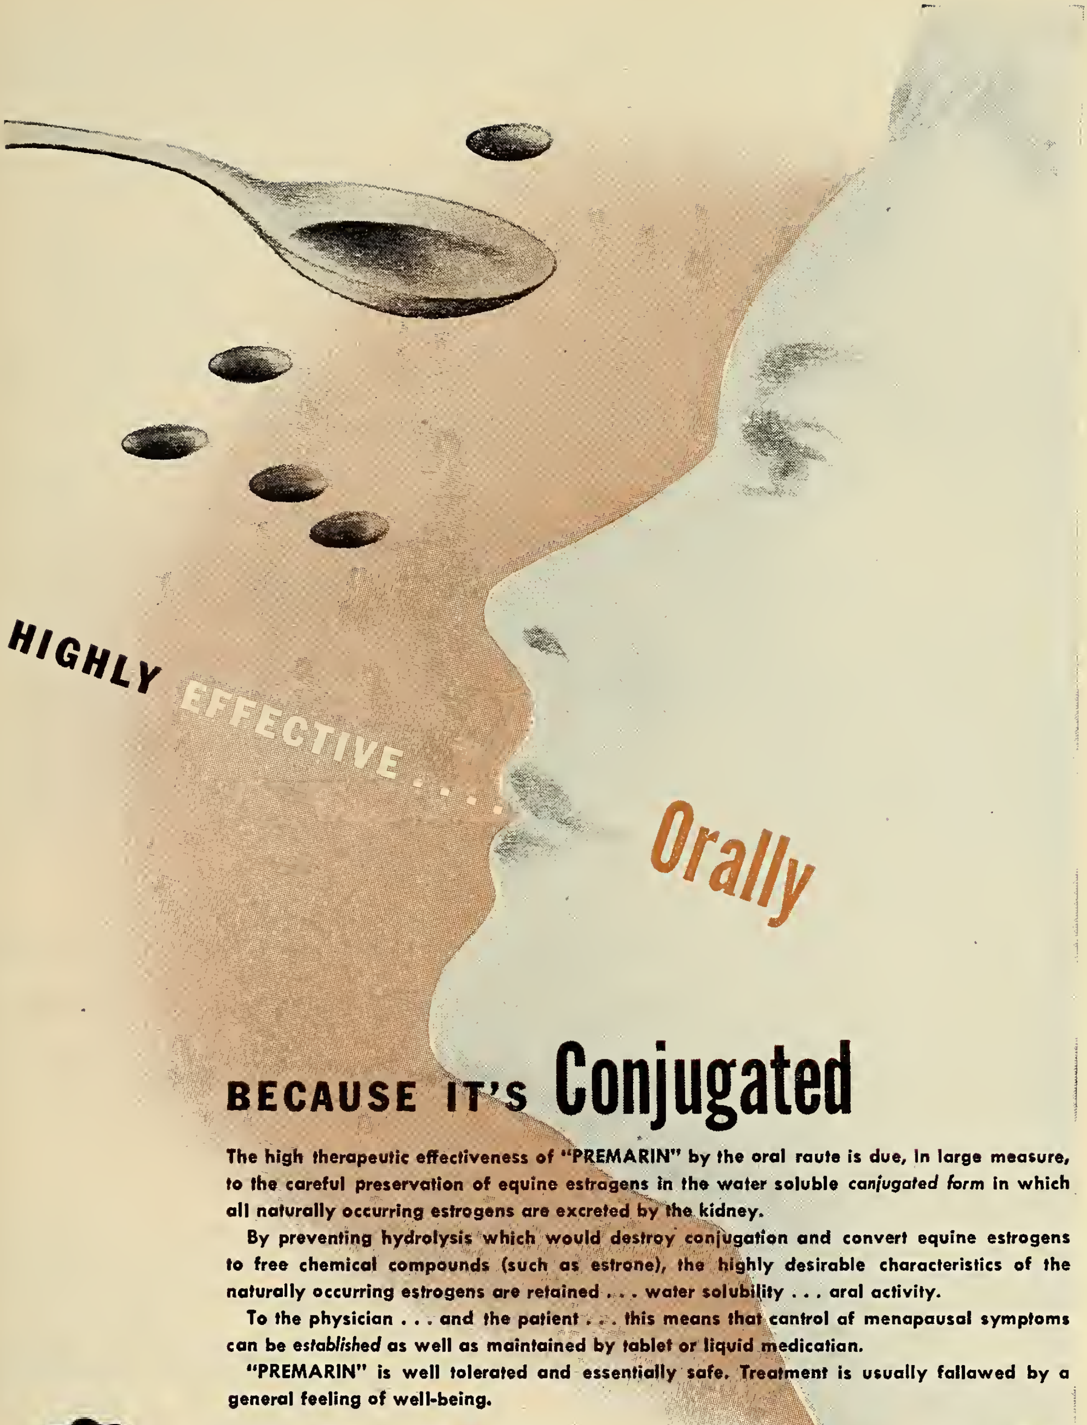
Office or home treatment now becomes practicable through administration of Penicillin in Oil and Wax as developed by Captain M. J. Romansky (M.C.) at the Walter Reed General Hospital, Washington, D. C. With this preparation it is possible to hold a penicillin therapeutic blood level by one injection in 24 hours, thus replacing the previous use of 8 injections of penicillin in saline over 24 hours.

There is usually less discomfort to the patient, and hence better cooperation. Also, by eliminating repeated injections the cost of treatment to the patient is lowered. and there is an appreciable saving in physicians' and nurses' time. This can be readily attained by the single injection of 1 cc. of 300,000 units in the oil-beeswax medium—known as Romansky formula, Bristol.

Bristol Laboratories now offer the Romansky formula with calcium penicillin. Due to special processing, the Bristol preparation is especially easy to inject. Write for new literature.

BRISTOL
LABORATORIES
INCORPORATED

SYRACUSE 1, NEW YORK



BECAUSE IT'S Conjugated

The high therapeutic effectiveness of "PREMARIN" by the oral route is due, in large measure, to the careful preservation of equine estrogens in the water soluble *conjugated form* in which all naturally occurring estrogens are excreted by the kidney.

By preventing hydrolysis which would destroy conjugation and convert equine estrogens to free chemical compounds (such as estrone), the highly desirable characteristics of the naturally occurring estrogens are retained . . . water solubility . . . oral activity.

To the physician . . . and the patient . . . this means that control of menopausal symptoms can be *established* as well as maintained by tablet or liquid medication.

"PREMARIN" is well tolerated and essentially safe. Treatment is usually followed by a general feeling of well-being.

AYERST, McKENNA & HARRISON LIMITED • 22 E. 40TH STREET • NEW YORK 16, N. Y.

For congestive heart failure:

NEXT IN IMPORTANCE TO DIGITALIS

In many cases of congestive heart failure mercurial diuretics are next in importance to digitalis in maintaining the patient's comfort and prolonging life.

Following an injection of Salyrgan-Theophylline in patients with marked edema the urinary output frequently amounts to three or four liters in twenty-four hours.

Through such diuresis the heart is relieved of the added burden of propelling the blood through the compressed blood vessels. The blood volume is decreased, and in all probability the efficiency of the heart is increased by elimination of myocardial edema.

•

Salyrgan-Theophylline is available in ampuls of 1 cc. and 2 cc. for intramuscular or intravenous administration . . . For oral use (as an adjunct to decrease the frequency of injections and when parenteral therapy is impracticable) tablets in bottles of 25, 100 and 500.

ACCEPTED AMERICAN MEDICAL ASSN.

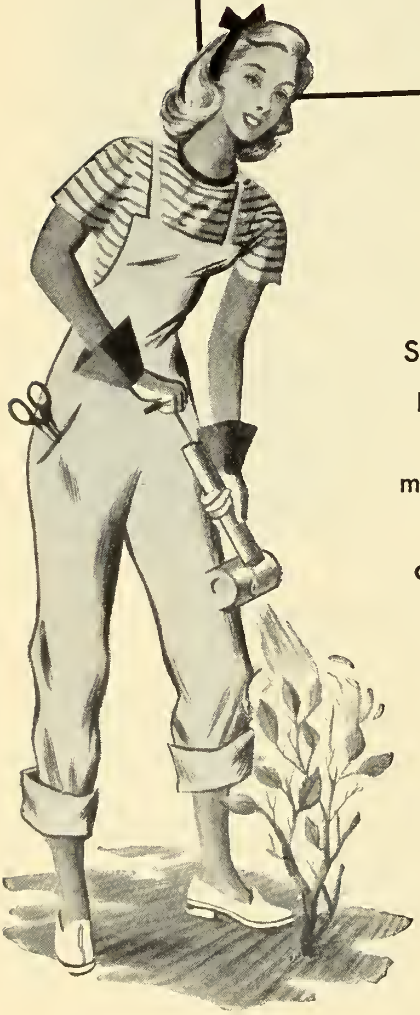
YOU CAN'T OVERRATE THE VALUE OF CONTROL



You probably know first-hand that it takes constant vigilance and scientific care to be sure of getting best results from your garden.

So, too, in the laboratory—in developing dependable pharmaceuticals. That's why quality control holds such a dominant position among the operations in modern U.D. research and production plants. From raw material inspection to final checking, every step of manufacture is guarded by one of the most detailed and successful control systems in the industry. Moreover, each finished U.D. formula is separately analyzed by the Formula Control Committee composed of doctors, chemists and pharmacists.

You may always be certain that your orders are filled with ingredients unexcelled in purity and potency when you indicate U.D. pharmaceuticals. Convenient Rexall Drug Stores provide these products—and offer skill and complete drug service to match their quality.

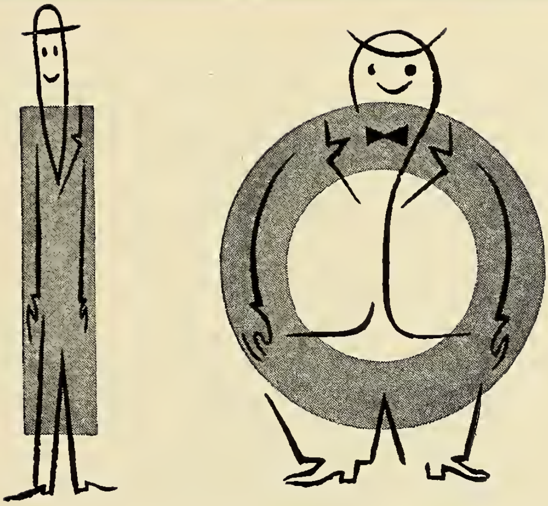
a common denominator for all restricted diets



All restricted diets must have one thing in common—vitamin adequacy—lest the patient's quest be thwarted by deficiency. Almost all restricted therapeutic diets have been found deficient in one or more of the essential vitamins. Supplementation is therefore mandatory in diets prescribed for obesity, allergies, peptic ulcer, and diabetes.[1] Easy to remember, easy to take, Upjohn vitamin preparations are potent, low cost aids in maintaining optimal vitamin intake during dietotherapy.

TODAY, the physician treating diabetics, has the choice of three types of insulin. One insulin is rapid-acting but short-lived. Another is slow-acting but prolonged. Between them is the new 'Wellcome' Globin Insulin with Zinc, moderately prompt in starting, yet capable of sustained effect *for sixteen or more hours.* Such intermediate action is sufficient to cover the periods of maximum carbohydrate intake, and diminished enough by nighttime to minimize the likelihood of nocturnal reactions. Physicians do well to consider all *three* insulins when treating their diabetic patients.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties.

Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in the Wellcome Research Laboratories, Tuckahoe, New York. U.S. Patent No. 2,161,198.

Available in vials of 10 cc., 80 units in 1 cc., and vials of 10 cc., 40 units in 1 cc. Literature on request. *'Wellcome' Trademark Registered.*

In the severe depressions of the menopause marked by apathy and psychomotor retardation

Many women in the climacteric period develop a true reactive depression, characterized by apathy, psychomotor retardation and despondency.

- This depressive syndrome is frequently progressive; and, unless promptly and effectively treated, may seriously impair the patient's normal capacity for useful living.
- In such cases, Benzedrine Sulfate helps to reawaken mental alertness and optimism, and to restore the savor and zest of life—especially when administered in conjunction with such fundamental measures as electric shock and estrogenic therapy.
- Obviously, Benzedrine Sulfate should not be used for the casual case of low spirits or normal physiologic depression, as distinguished from true prolonged mental depression.

full recovery through a miracle of distribution

THIS LITTLE GIRL will be up tomorrow. Ten days ago she was suddenly stricken with streptococcic septicemia. Her physician needed penicillin—plenty of it, right away. Fortunately, the drug store had a sufficient quantity in stock to start treatment. The pharmacist hurriedly called his service wholesaler, and an adequate supply of Penicillin, Lilly, was promptly available.

In over two hundred wholesale houses, in every corner of the nation, Penicillin, Lilly, is kept properly stored, ready for immediate delivery. Quick availability is vitally important in cases of desperate illness. Specify Penicillin, Lilly, through your favorite prescription pharmacy.

THE TREATMENT OF PNEUMOCOCCIC AND STAPHYLOCOCCIC MENINGITIS WITH PENICILLIN AND SULFONAMIDES

Report of Twenty Cases

WENDELL H. HALL, M.D., JOHN ALDEN, M.B., GEORGIE M. BURT, M.D. and
WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

THIS report is concerned with the results of treatment with penicillin in seventeen cases of pneumococcic meningitis and three cases of staphylococcic meningitis. While the number of cases is not large the results are quite encouraging when compared to those obtained before penicillin became available. However, an analysis of the present cases and a review of the literature indicates that pneumococcic meningitis is still a serious clinical problem.

Prior to the general use of the sulfonamides, recovery from pneumococcic meningitis was rarely encountered. Following the introduction of the sulfonamides, especially sulfapyridine, the mortality rate from this disease declined. But even after the completion of an evaluation of other sulfonamides, such as sulfadiazine, sulfathiazole and sulfamerazine, all utilized with and without specific antipneumococcic serum, the results have not been very encouraging. It would appear that the over-all case mortality rate of pneumococcic meningitis following treatment with the sulfonamides varies between 60 and 80 per cent. The former figure approximates the experience at the University of Minnesota Hospitals, while the latter reflects the results of Dingle and Finland[3] in Boston. The results with penicillin would indicate that the mortality rate is around 50 per cent.[7] A summary of 162 patients with pneumococcic meningitis treated with penicillin in different parts of the country reveals that eighty-eight patients died, giving a case mortality rate of 54.3 per cent (Table I). It is of signif-

TABLE II. SUMMARY OF SEVENTEEN PATIENTS WITH PNEUMOCOCCIC MENINGITIS TREATED WITH PENICILLIN

Patient No.	Age and Sex	Duration of Symtoms Prior to Therapy with Penicillin	Primary Focus	Type of Pneumococcus		Treatment Prior to Penicillin	Total Units of Penicillin		Simultaneous Sulfonamide Therapy	Number Days in Hospital	Result	COMMENT
				C.S.F.	Blood		Parenterally	Intrathecally				
1	47 yrs. Male	3 days	Pneumonia Otitis media	III	III	SD., SM.	2,355,000 in 27 days	235,000 in 14 days	SM.–51 grams in 11 days ST.–1 gram in 1 day	37	Recovery	No residual. Cerebrospinal fluid sterile 12 hours after first dose of penicillin.
2	60 yrs. Male	2 days	Otitis media	III	III		1,728,000 in 28 days	90,000 in 7 days	SM.–10 grams in 3 days ST.–2.6 grams in 4 days	56	Recovery	Slight residual weakness right side. Myringotomy day preceding therapy with penicillin. Mastoidectomy 1st day of penicillin therapy. 5th day therapy bronchopneumonia. 7th day evidence left temporoparietal brain abscess. 24th day craniotomy for subdural abscess. 39th day second craniotomy.
3	2½ mos. Female	4 days		V			271,000 in 12 days	69,000 in 12 days	SD.–14 grams in 14 days	14	Recovery	No residual. Temp. normal in 5 days.
4	4½ yrs. Male	4 days	Otitis media	V		SD. and myringotomy	397,000 in 15 days	75,000 in 7½ days	SD.–49 grams in 16 days	14	Recovery	Residual of marked hearing loss.
5	5½ yrs. Male	35 days	Otitis media	VI		SD.–181 grams in 32 days	652,000 in 10 days			42	Died	No penicillin intrathecally. Organisms persisted in cerebrospinal fluid. Autopsy—thick exudate base of brain; dilated 3rd ventricle; ventricles filled with purulent material; no gross abscesses; normal mastoids.
6	25 yrs. Female	7 days	Otitis media	VII		SD. for 7 days; myringotomy	590,000 in 10 days	100,000 in 5 days	SM.–58 grams in 11 days	17	Recovery	No residual. On entry to hospital stuporous (diabetic ketosis); mastoidectomy 5th day in hospital with coag. pos. staph. from exudate.
7	6 mos. Male	3 days	Pneumonia	XII	XII 2 cols. per c.c.	SM.	443,000 in 21 days	78,500 in 16 days	SM.–7 grams in 6 days	27	Recovery	No residual. Intrathecal block on 6th day of treatment necessitating 3 intracisternal injections of penicillin.
8	7 mos. Male	5 days	Otitis media	XII		SP., bilateral myringotomy	160,000 in 12 days	27,000 in 12 days		12	Recovery	No residual. Rise in cerebrospinal fluid cell count first 3 days of treatment. Convulsions 4th day. 3000 units intracisternally.
9	46 yrs. Female	2 days	Otitis media	XII	XII		520,000 in 2 days	50,000 in 2 days	SD.–19 grams in 2 days	2	Died	Failed to respond. Autopsy-purulent exudate in subarachnoid space; hemorrhagic pneumonia.
10	48 yrs. Male	4 days	Pneumonia	XII	XII	SD.	754,000 in 10 days	241,000 in 9 days	SD.–142 grams in 10 days	10	Died	Temporary improvement. Received penicillin intracisternally. Autopsy—mild meningitis base of brain; cerebrospinal fluid sterile.
11	5 mos. Male	15 days	Otitis media	XVIII		SD., SM., myringotomy	337,000 in 12 days	35,000 in 4 days	SD.–5.5 grams in 5 days	18	Recovery	No residual. Meningitis developed while patient receiving penicillin intramuscularly for otitis media. Mastoidectomy 1st day of therapy—culture sterile. Prompt response to penicillin intrathecally.
12	6 mos. Male	2 days		XIX	XIX 200–250 cols. per c.c.		672,000 in 22 days	30,000 in 7 days	SD.–26 grams in 16 days	36	Recovery	No residual.
13	57 yrs. Male	3 days	Pneumonia	XIX	XIX		885,000 in 10 days	140,000 in 9 days	SD.–170 grams in 18 days	28	Died	Death due endocarditis with rupture of aortic cusp; blood sterile; unresolved pneumonia rt. upper lobe; no evidence of meningitis.
14	7 mos. Female	2 days	Otitis media	XXI		SD.	486,000 in 21 days	54,000 in 17 days	SD.–47.75 grams in 20 days	41	Recovery	Severe residual cerebral damage. Probably diminution of vision and hearing.
15	30 yrs. Male	13 days		XXIII	XXIII	Sulfonamide for 15 days	6,514,000 in 58 days	340,000 in 26 days	SD.–293 grams in 35 days	44	Recovery	One month prior to entry treated for meningitis with penicillin intrathecally and intramuscularly (doses not known). One month later second relapse. Cerebrospinal fluid sterile. Evidence of encephalitis. Third relapse. Biopsy of rt. and left parietal lobes of brain showed encephalitis. Complete recovery with no neurologic residual.
16	58 yrs. Female	3 days	Otitis media	XXXII	XXXII 83 cols. per c.c.		872,500 in 14 days	120,000 in 5 days		22	Recovery	No residual. Myringotomy 2nd day penicillin therapy.
17	10 yrs. Male	35 days	Skull fracture through sinus	XXXIII		SD. and ST. for 29 days	912,300 in 28 days		SP.–21.5 grams in 13 days SD.–13.75 grams in 5 days	17	Recovery	No residual. Improvement following SD. Also received 100,000 units type XXXIII antipneumococcic rabbit serum intravenously and intrathecally without definite improvement. Penicillin given parenterally without benefit. Operative drainage of sinuses followed by prompt improvement and recovery.

TABLE III. AGE DISTRIBUTION OF SEVENTEEN PATIENTS WITH PNEUMOCOCCIC MENINGITIS

Age	Pneumococcic Types	No. Cases	No. Died
0-12 mos.	V, XII, XVIII, XIX, XXI	6	0
1-5 yrs.	V	1	0
5-10 yrs.	VI	1	1
10-20 yrs.	XXXIII	1	0
20-50 yrs.	III, VII, XII, XXIII	5	2
50-70 yrs.	III, XIX, XXXII	3	1

icance that rates considerably lower than this were reported by two groups. Waring and Smith[20] in Baltimore treated twelve patients with penicillin and sulfadiazine or sulfapyrazine and had but one death. Four of the patients received specific antipneumococcic serum in addition but this apparently had little effect on the outcome. These outstanding results stand out in marked contrast to previous experience. Up to 1937, 179 cases of pneumococcic meningitis were treated at the Harriet Lane Home and Sydenham Hospital with a mortality rate of 100 per cent. When sulfanilamide became available, twenty-five patients were treated and twenty-three died. From 1938 to 1943 a total of sixty patients were given sulfapyridine, sulfadiazine or sulfathiazole with and without antipneumococcic serum, and the mortality rate was 58 per cent. They conclude with the recommendation that penicillin and sulfadiazine or sulfapyrazine should be utilized in the treatment of pneumococcic meningitis. Harford and his associates[6] in St. Louis treated nine patients with penicillin and reported but one death. They attribute this favorable outcome, in part, to the fact that five of the patients, in addition to receiving penicillin, had had mastoidectomies, which succeeded in eradicating the primary foci.

A less frequently encountered form of bacterial meningitis is that caused by staphylococci. Although the sulfonamides are less satisfactory antistaphylococcic agents than penicillin, there are several recorded instances of patients recovering from staphylococcic meningitis as a result of sulfonamide therapy, particularly following the use of sulfathiazole.[8,12,13,14,16] There are at least nine recorded recoveries from staphylococcic meningitis following the administration of penicillin.[9,10,18,19]

TABLE IV. PRIMARY FOCI IN SEVENTEEN PATIENTS WITH PNEUMOCOCCIC MENINGITIS

Focus	No. Cases
Otitis media	10
Pneumonia	3

Unknown	3

Pneumococcic Meningitis

In the present series of seventeen patients with pneumococcic meningitis there were thirteen who recovered and four who died giving a case mortality rate of 23.5 per cent. Although the total number of cases is not large there has been a significant reduction of the death rate from this disease associated with the administration of penicillin. A summary of the pertinent clinical data regarding these patients is shown in Table II.

Age Incidence.—The age distribution of the seventeen patients is given in Table III. It is of particular interest that there were six patients under twelve months of age and all of them recovered. There were three patients over fifty years of age with two recoveries. It is well established that pneumococcic meningitis is an extremely serious and frequently fatal disease in infants and in the aged. The present results indicate that penicillin is beneficial in these extremes of life.

Types of Pneumococci.—As seen in Table III no particular type of pneumococcus was predominant as the cause of meningitis.

Primary Foci.—The probable primary focus of infection was established in fourteen of the seventeen patients as shown in Table IV. Of the ten patients with otitis media, myringotomies were carried out in six individuals, all of whom recovered. Two of these six patients also had mastoidectomies. It is not unlikely that eradication of the primary foci in these individuals contributed to the recovery of the patients, a factor which has also been considered by others[6] in the treatment of patients with penicillin. Patient 2 (Table II) was a sixty-year-old patient under the care of Dr. Jay C. Davis of Minneapolis. He was desperately ill with a meningitis due to type III pneumococci, and it is very doubtful if therapy with penicillin would have resulted in a favorable outcome without radical surgical interference to remove purulent material, which included a myringotomy, mastoidectomy, and two craniotomies for a subdural abscess. Drainage of a primary focus was undoubtedly responsible for recovery in patient 17 (Table II), a patient of Dr. Ray Shannon of Saint Paul. The patient, a ten-year-old boy, developed meningitis due to type XXXIII pneumococci following a fracture of the skull. Roentgenograms revealed a fracture running diagonally upward from the region of the right ethmoid cells and along the medial wall of the right orbit into the right frontal bone for two inches. This patient was the first one of the seventeen patients to receive penicillin and the material was only given intravenously. In addition he received therapy with sulfonamides and type-specific antipneumococcic serum. Because his condition was not improving, on the forty-seventh day of his illness both antra were drained, as well as the sphenoid and ethmoid sinuses. All sinuses were apparently the site of suppuration and following drainage recovery was progressive.

Fatal Cases.—Patient 5 (Table II) was treated with penicillin through the co-operation of Dr. E. J. Huenekens of Minneapolis. He had received sulfadiazine for thirty-two days without improvement and then penicillin was administered intravenously over a period of ten days. No penicillin was injected directly into the subarachnoid space. His condition became progressively worse and he expired. Postmortem examination revealed a thick exudate involving the meninges of the brain. It is possible that penicillin given intrathecally would have caused a more favorable outcome. Patient 9 failed to respond to combined therapy with sulfadiazine, and penicillin administered intramuscularly and intrathecally. Patient 10 was treated similarly, except that penicillin was injected intracisternally, and experienced temporary improvement but death was precipitated by meningitis and a hemorrhagic pneumonia. Patient 13 had apparently recovered completely from meningitis and died of cardiac failure following rupture of an aortic cusp. This patient had an endocarditis although organisms were not recovered from the blood.

Residual Involvement of Central Nervous System.—Although it can be anticipated that more patients will recover from pneumococcic meningitis than prior to the introduction of penicillin, serious and permanent damage to the central nervous system may result. Two patients, at least, were left with marked diminution of hearing (Patients 4 and 14). In addition, patient 14 probably had some loss of vision. In spite of an extremely stormy clinical course, which included several operative procedures, patient 2 recovered with only a slight residual weakness of the right side of the body. Patient 15 had three relapses with what was at first considered to be meningitis but exploratory operation defined these relapses as being associated with an encephalitis. The patient finally recovered completely without any neurologic residual.

Treatment.—When penicillin first became available in this clinic for the treatment of pneumococcic meningitis it was not clearly established whether the drug passed the blood-brain barrier and appeared in the cerebrospinal fluid following intramuscular or intravenous administration. Therefore, the first two individuals (patients 5 and 17) did not receive intrathecal injections of penicillin. Subsequently, Rammelkamp and Keefer[13] observed that penicillin introduced intravenously into normal human beings did not pass the blood-brain barrier. Later, Rosenberg and Sylvester[14] reported that the intramuscular injection of penicillin in patients with meningococcic meningitis was followed by the appearance of appreciable quantities of penicillin in the cerebrospinal fluid. Rammelkamp and Keefer[12] pointed out that penicillin could be safely introduced intrathecally, such a procedure provoking only an increase in leukocytes in the cerebrospinal fluid and, occasionally, headaches. In the present study, after therapeutic failures had resulted with the first two cases, it appeared logical and desirable to administer penicillin intravenously or intramuscularly and also intrathecally. Early reports indicated that the treatment of patients having pneumococcic meningitis with penicillin alone left much to be desired. The case mortality rates still exceeded 50 per cent. In view of this, the policy established in this clinic was to administer both a sulfonamide and penicillin to patients with pneumococcic meningitis. Either sulfadiazine or sulfamerazine or their sodium salts were given orally or intravenously, and penicillin was injected intravenously or intramuscularly, and also into the subarachnoid space.

For adults, 10,000 Oxford units of penicillin were dissolved in sterile physiological saline solution and injected intrathecally after an equivalent amount or more of cerebrospinal fluid was withdrawn. This was repeated every twelve thours for the first few days, and then as improvement took place, injections were given every twenty-four hours. In the patients who recovered, and exclusive of patient 15, intrathecal therapy was carried out for an average of seven days. An initial dose of 50,000 to 75,000 units of penicillin was administered as an intravenous drip, which was followed by the intramuscular injections of 10,000 to 50,000 units every three hours. The duration of treatment with penicillin averaged twenty-one days with an average total of about 1,500,000 units given to the patients who recovered. It is to be noted again that patients 5 and 17 did not receive penicillin intrathecally and as a result neither patient manifested improvement. Sulfadiazine or sulfamerazine was given concurrently in doses which maintained a blood concentration around 10 mgs. per 100 c.c. One individual (patient 16) did not receive treatment with a sulfonamide, and she recovered.

In the infants and small children, from 3,000 to 5,000 units of penicillin were introduced intrathecally every twelve hours during the initial days of therapy, and then daily. The average period of intrathecal therapy was ten days. From 3,000 to 4,000 units of penicillin were given intramuscularly every three hours. The average total amount of penicillin utilized was 450,000 units which was administered over a period of sixteen to seventeen days. Sulfadiazine or sulfamerazine was employed as in the adults in doses which provided a blood concentration of 10 mgs. per 100 c.c.

There are some reports[11,14] in which the necessity of injecting penicillin intrathecally in the treatment of meningitis is questioned. While there is no doubt that penicillin will appear in the cerebrospinal fluid in patients with inflamed meninges when the drug is given intramusculary or intravenously, and that because of the extreme susceptibility of meningococci to penicillin, meningococcic meningitis may be treated without the direct introduction of penicillin into the subarachnoid space, the foregoing experience in this clinic indicates the desirability of using penicillin intrathecally in the treatment of pneumococcic meningitis. Experience with patient 11 illustrates in a dramatic fashion the value of giving penicillin intrathecally. The patient, a five-month-old male child, had otitis media on the left six weeks before entry to the hospital. Following treatment with sulfadiazine, the symptoms and fever promptly subsided. Two weeks later, otitis media recurred and he again appeared to respond quickly to therapy with sulfadiazine. Two weeks later, the same ear was again involved and a myringotomy revealed a purulent discharge. The infant did not respond satisfactorily to either sulfadiazine or sulfamerazine and hospitalization was advised. Treatment with penicillin was instituted, 5,000 units being given intramuscularly every three hours. However, the child failed to improve and on the third day of penicillin therapy there were signs of meningeal irritation and a lumbar puncture yielded type XVIII pneumococci. Then 5,000 units of penicillin were introduced into the subarachnoid space. Although a mastoidectomy was performed no evidence of infection was demonstrated. Following the initial intrathecal injection of penicillin there was prompt clinical improvement, and a culture of the cerebrospinal fluid twenty-four hours later remained sterile. Three more doses of 10,000 units each were given on the three succeeding days. The baby was also given sulfadiazine orally and penicillin intramuscularly. A total of 372,000 units of penicillin was utilized and the child made an uneventful recovery.

It has been of importance to determine whether the salts of penicillin have an irritative effect upon the central nervous system and the meninges. Walker and Johnson[19] observed that the application of commercial penicillin to the cerebral cortex of cats, dogs, monkeys and human beings produced convulsive manifestations. The convulsive and antibiotic factors appeared to be closely related. Sweet and his associates[18] report severe neurologic reactions following the intrathecal injection of penicillin in human patients with pneumococcic meningitis, but relatively high doses of penicillin were used. Likewise, a single instance has been reported by Siegal.[16] No untoward reactions followed the intrathecal injection of penicillin in this clinic, and this may be related to the fact that the doses of penicillin rarely exceeded 10,000 units daily or twice daily.

TABLE V. SUMMARY OF THREE PATIENTS WITH STAPHYLOCOCCIC MENINGITIS TREATED WITH PENICILLIN

Patient No.	Age and Sex	Duration of symptoms Prior to Therapy with Penicillin	Total Units of Penicillin		Simultaneous Sulfonamide Therapy	Number of Days in Hospital	Results	Comment
			Parenterally	Intrathecally				
1	3 weeks male	3 days	277,750 in 13 days	66,000 in 13 days	9 grams SD. in 18 days	42	Died	Primary focus was meningomyelocele. *Staphylococci* and *E. coli* in CSF. Former eradicated from CSF. but E. coli persisted. Autopsy—revealed bronchopneumonia and meningitis.
2	7 weeks male	5 days	161,000 in 20 days	38,000 in 19 days	19 grams ST. in 27 days; 1 gram SD. in 1 day	31	Recovery	No residual.
3	8 weeks male	2 days	967,000 in 54 days	120,000 in 32 days	44.5 grams SD. in 54 days	57	Recovery	No residual. Developed epidural abscess at site of lumbar intrathecal injections which was eradicated by local use of penicillin.

McCune and Evans[9] have pointed out that when penicillin is injected intrathecally in the lumbar region minimal amounts were found in the fluid of the ventricles two hours later, and have suggested that on some occasions it may be necessary to introduce penicillin directly into the ventricles. The results of White and his group[21] reveal a lower case mortality rate in pneumococcic meningitis when penicillin was introduced into a higher site than the lumbar region, and they have recommended that the penicillin should be given into the cisterna magna.

Summary

The following specific therapeutic recommendations are essentially those being carried out at the University of Minnesota Hospitals at the present time.

1. Adults. As soon as the diagnosis is established sulfadiazine or sulfamerazine is given orally or parenterally so that blood concentrations of at least 10 mgs. per 100 c.c. are quickly established and sustained. It is doubtful whether higher levels are necessary. Penicillin is given intramuscularly in doses of 20,000 units every two hours for the first twenty-four hours, and then the same dose is given every three hours. Penicillin therapy is continued until the temperature has remained normal for forty-eight hours and blood cultures remain sterile. Sulfonamide therapy is carried out for at least one week after all signs of the infection have abated and the cerebrospinal fluid is normal. Penicillin is injected every twenty-four hours intrathecally in the lumbar region employing 10,000 units in 10 c.c. of sterile physiologic saline solution. This penicillin solution is introduced immediately after the withdrawal of at least 10 c.c. of cerebrospinal fluid. Intrathecal therapy should be continued as long as organisms are present in the cerebrospinal fluid. If the fluid is sterile, intrathecal injections should be given as long as the fluid is cloudy or the concentration of sugar is diminished. In desperate situations it may be advisable to inject the penicillin into the cisterna magna.

2. Infants and Small Children. Essentially the same procedure is carried out, except that the doses of penicillin given intramuscularly are 5,000 units, and 2,500 to 5,000 units are injected intrathecally.

Staphylococcic Meningitis

Three patients with staphylococcic meningitis were treated with penicillin. They were male infants, three weeks, seven weeks and eight weeks of age. Two of three infants recovered completely. A summary of the clinical data on these patients is given in Table V. The one infant three weeks old that died had a meningomyelocele as a primary focus of infection. Staphylococci and *E. coli* were isolated from the cerebrospinal fluid. Following the parathecal and intrathecal use of penicillin and the oral administration of sulfadiazine, the staphylococci were eradicated from the cerebrospinal fluid but *E. coli* persisted until death. Postmortem examination revealed bronchopneumonia and purulent meningitis.

These infants were treated in practically the same manner as described for those having pneumococcic meningitis. However, it was necessary to administer daily up to 3,000 units of penicillin intrathecally for a longer period before the cerebrospinal fluid remained sterile. It is of interest that patient 3 developed an epidural abscess at the site of repeated lumbar punctures which was eradicated by the local instillation of penicillin.

It is recommended that staphylococcic meningitis be treated in the same manner as pneumococcic meningitis, that is, sulfadiazine and penicillin should be used systemically and penicillin should be injected intrathecally. That treatment with penicillin intrathecally is probably essential is borne out by the experimental observations of Pilcher and Meacham.[19] Experimental staphylococcic meningitis in dogs was not benefited by the intravenous use of penicillin, but the intrathecal injection of penicillin was followed by a mortality rate of 54 per cent as compared to 93 per cent in infected controls.

Comment

While treatment with penicillin and the sulfonamides has afforded a more favorable outlook for patients with suppurative meningitis, continued improvement in the case mortality rate and the ultimate outcome of the patient who recovers are dependent upon other factors. It is extremely important that a diagnosis should be established early in the course of the disease and that favorable facilities should be available for early treatment. If the initial examination of the cerebrospinal fluid reveals evidence of a suppurative involvement of the meninges, but precise bacteriologic information must await further study, one is justified in beginning treatment immediately. Following identification of the etiologic micro-organism, the course of treatment may be altered if necessary. Meticulous nursing care and supportive measures are stressed only because of their importance. The attending clinician should examine the patient at frequent intervals with particular attention to suppurative foci which may require surgical intervention for eradication. The state of the patient's hydration and nutrition should be evaluated and corrected when indicated. In conclusion, attention to the foregoing measures in treatment has contributed to the favorable outcome of the majority of patients reported at this time.

Summary

1. Seventeen patients with pneumococcic meningitis were treated with penicillin and thirteen recovered. Sixteen of the seventeen patients received both penicillin and sulfadiazine or sulfamerazine.

2. Three infants with staphylococcic meningitis were treated with a combination of penicillin and sulfonamides and two recovered.

3. It is recommended that in the treatment of suppurative meningitis due to pneumococci or staphylococci penicillin should be administered intravenously or intramuscularly and intrathecally. In addition, sulfadiazine or sulfamerazine should be given orally or parenterally, but not intrathecally.

4. The importance of early diagnosis, supportive treatment and eradication of suppurative foci are stressed.
